The OpenGL® Graphics System:
A Specification
(Version 3.2 (Compatibility Profile) - December 7, 2009)

Mark Segal
Kurt Akeley

Editor (version 1.1): Chris Frazier
Editor (versions 1.2-3.2): Jon Leech
Editor (version 2.0): Pat Brown
# Contents

1 **Introduction** 1
  1.1 Comments on edits to the OpenGL 3.1 Specification . . . . . . . . 1
  1.2 Formatting of Optional Features . . . . . . . . . . . . . . . . 1
  1.3 What is the OpenGL Graphics System? . . . . . . . . . . . . . 2
  1.4 Programmer’s View of OpenGL . . . . . . . . . . . . . . . . . 2
  1.5 Implementor’s View of OpenGL . . . . . . . . . . . . . . . . . 2
  1.6 Our View . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 3
  1.7 The Deprecation Model . . . . . . . . . . . . . . . . . . . . . . 3
  1.8 Companion Documents . . . . . . . . . . . . . . . . . . . . . . . 3
    1.8.1 OpenGL Shading Language . . . . . . . . . . . . . . . . 3
    1.8.2 Window System Bindings . . . . . . . . . . . . . . . . . 4

2 **OpenGL Operation** 5
  2.1 OpenGL Fundamentals . . . . . . . . . . . . . . . . . . . . . . . 5
    2.1.1 Floating-Point Computation . . . . . . . . . . . . . . . . 7
    2.1.2 16-Bit Floating-Point Numbers . . . . . . . . . . . . . . 8
    2.1.3 Unsigned 11-Bit Floating-Point Numbers . . . . . . . . . 9
    2.1.4 Unsigned 10-Bit Floating-Point Numbers . . . . . . . . . 9
    2.1.5 Fixed-Point Data Conversions . . . . . . . . . . . . . . . . 10
  2.2 GL State . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 12
    2.2.1 Shared Object State . . . . . . . . . . . . . . . . . . . . . 13
  2.3 GL Command Syntax . . . . . . . . . . . . . . . . . . . . . . . . 13
  2.4 Basic GL Operation . . . . . . . . . . . . . . . . . . . . . . . . 15
  2.5 GL Errors . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 17
  2.6 Begin/End Paradigm . . . . . . . . . . . . . . . . . . . . . . . . 18
    2.6.1 Begin and End . . . . . . . . . . . . . . . . . . . . . . . 22
    2.6.2 Polygon Edges . . . . . . . . . . . . . . . . . . . . . . . 29
    2.6.3 GL Commands within **Begin/End** . . . . . . . . . . . . . 29
  2.7 Vertex Specification . . . . . . . . . . . . . . . . . . . . . . . . 30
2.8 Vertex Arrays .......................................................... 34
  2.8.1 Drawing Commands ............................................. 40
2.9 Buffer Objects ......................................................... 47
  2.9.1 Creating and Binding Buffer Objects ......................... 47
  2.9.2 Creating Buffer Object Data Stores ......................... 50
  2.9.3 Mapping and Unmapping Buffer Data ......................... 52
  2.9.4 Effects of Accessing Outside Buffer Bounds ............... 56
  2.9.5 Copying Between Buffers ..................................... 56
  2.9.6 Vertex Arrays in Buffer Objects ............................. 57
  2.9.7 Array Indices in Buffer Objects ............................. 58
  2.9.8 Buffer Object State .......................................... 58
2.10 Vertex Array Objects .............................................. 59
2.11 Rectangles .............................................................. 60
2.12 Fixed-Function Vertex Transformations .......................... 60
  2.12.1 Matrices ....................................................... 61
  2.12.2 Normal Transformation ...................................... 66
  2.12.3 Generating Texture Coordinates ............................. 68
2.13 Fixed-Function Vertex Lighting and Coloring ................... 70
  2.13.1 Lighting ....................................................... 72
  2.13.2 Lighting Parameter Specification ........................... 76
  2.13.3 ColorMaterial ................................................ 77
  2.13.4 Lighting State ................................................ 80
  2.13.5 Color Index Lighting ........................................ 80
  2.13.6 Clamping or Masking ....................................... 81
2.14 Vertex Shaders ....................................................... 82
  2.14.1 Shader Objects ............................................... 82
  2.14.2 Program Objects ............................................. 84
  2.14.3 Vertex Attributes ........................................... 86
  2.14.4 Uniform Variables .......................................... 89
  2.14.5 Samplers ..................................................... 106
  2.14.6 Varying Variables .......................................... 106
  2.14.7 Shader Execution ............................................ 109
  2.14.8 Required State .............................................. 116
2.15 Geometry Shaders ................................................... 118
  2.15.1 Geometry Shader Input Primitives ......................... 118
  2.15.2 Geometry Shader Output Primitives ....................... 120
  2.15.3 Geometry Shader Variables ................................ 120
  2.15.4 Geometry Shader Execution Environment ................. 121
2.16 Coordinate Transformations ...................................... 126
  2.16.1 Controlling the Viewport .................................. 126

LIST OF FIGURES

4.3 Operation of CopyPixels. ........................................... 316

5.1 Map Evaluation. ...................................................... 346
5.2 Feedback syntax. ..................................................... 355
List of Tables

2.1 GL command suffixes ........................................ 14
2.2 GL data types ................................................ 16
2.3 Summary of GL errors ........................................ 19
2.4 Triangles generated by triangle strips with adjacency. ........ 28
2.5 Vertex array sizes (values per vertex) and data types .......... 36
2.6 Variables that direct the execution of InterleavedArrays. .. .... 45
2.7 Buffer object binding targets. ................................ 48
2.8 Buffer object parameters and their values. ....................... 49
2.9 Buffer object initial state. .................................... 51
2.10 Buffer object state set by MapBufferRange. .................. 54
2.11 Summary of lighting parameters. ............................. 73
2.12 Correspondence of lighting parameter symbols to names. ....... 78
2.13 OpenGL Shading Language type tokens ........................ 98
2.14 Transform feedback modes .................................... 131
2.15 Provoking vertex selection. ................................... 135
3.1 PixelStore parameters. ......................................... 170
3.2 PixelTransfer parameters. ..................................... 172
3.3 PixelMap parameters. .......................................... 173
3.4 Color table names. ............................................. 174
3.5 Pixel data types. .............................................. 185
3.6 Pixel data formats. ............................................ 186
3.7 Swap Bytes bit ordering. ....................................... 187
3.8 Packed pixel formats. .......................................... 189
3.9 UNSIGNED_BYTE formats. Bit numbers are indicated for each component. ........................................ 190
3.10 UNSIGNED_SHORT formats .................................... 191
3.11 UNSIGNED_INT formats ....................................... 192
3.12 FLOAT UNSIGNED_INT formats ............................... 193
## LIST OF TABLES

3.13 Packed pixel field assignments. ............................... 194
3.14 Color table lookup. ............................................ 201
3.15 Computation of filtered color components. .................. 202
3.16 Conversion from RGBA, depth, and stencil pixel components to internal texture, table, or filter components. .................. 214
3.17 Sized internal color formats. .................................. 219
3.18 Sized internal luminance and intensity formats. .......... 220
3.19 Sized internal depth and stencil formats. ................. 221
3.20 Generic and specific compressed internal formats. ......... 221
3.21 Internal formats for buffer textures ......................... 240
3.22 Texture parameters and their values. ......................... 241
3.23 Selection of cube map images. ................................. 243
3.24 Texel location wrap mode application. ....................... 248
3.25 Correspondence of filtered texture components to texture source components. ................................. 262
3.26 Texture functions REPLACE, MODULATE, and DECAL .... 262
3.27 Texture functions BLEND and ADD. ........................... 263
3.28 COMBINE texture functions. .................................. 264
3.29 Arguments for COMBINE_RGB functions. ..................... 265
3.30 Arguments for COMBINE_ALPHA functions. ................... 265
3.31 Depth texture comparison functions. .......................... 267
4.1 RGB and Alpha blend equations. ............................... 292
4.2 Blending functions. .............................................. 293
4.3 Arguments to LogicOp and their corresponding operations. 296
4.4 Buffer selection for the default framebuffer .................. 299
4.5 Buffer selection for a framebuffer object ..................... 299
4.6 DrawBuffers buffer selection for the default framebuffer ... 300
4.7 PixelStore parameters. .......................................... 310
4.8 ReadPixels index masks. ........................................ 314

Chapter 1

Introduction

This document describes the OpenGL graphics system: what it is, how it acts, and what is required to implement it. We assume that the reader has at least a rudimentary understanding of computer graphics. This means familiarity with the essentials of computer graphics algorithms as well as familiarity with basic graphics hardware and associated terms.

1.1 Comments on edits to the OpenGL 3.1 Specification

Changes in the most recent draft are typeset in magenta.
Material which has been deprecated from the OpenGL 3.0 specification is typeset in orange.
Older changes are typeset in purple.
Editorial comments and questions are typeset in blue.

1.2 Formatting of Optional Features

Starting with version 1.2 of OpenGL, some features in the specification are considered optional; an OpenGL implementation may or may not choose to provide them (see section 3.7.2).
Portions of the specification which are optional are so described where the optional features are first defined (see section 3.7.2). State table entries which are optional are typeset against a gray background.
1.3 What is the OpenGL Graphics System?

OpenGL (for “Open Graphics Library”) is a software interface to graphics hardware. The interface consists of a set of several hundred procedures and functions that allow a programmer to specify the objects and operations involved in producing high-quality graphical images, specifically color images of three-dimensional objects.

Most of OpenGL requires that the graphics hardware contain a framebuffer. Many OpenGL calls pertain to drawing objects such as points, lines, polygons, and bitmaps, but the way that some of this drawing occurs (such as when antialiasing or texturing is enabled) relies on the existence of a framebuffer. Further, some of OpenGL is specifically concerned with framebuffer manipulation.

1.4 Programmer’s View of OpenGL

To the programmer, OpenGL is a set of commands that allow the specification of geometric objects in two or three dimensions, together with commands that control how these objects are rendered into the framebuffer.

A typical program that uses OpenGL begins with calls to open a window into the framebuffer into which the program will draw. Then, calls are made to allocate a GL context and associate it with the window. Once a GL context is allocated, the programmer is free to issue OpenGL commands. Some calls are used to draw simple geometric objects (i.e. points, line segments, and polygons), while others affect the rendering of these primitives including how they are lit or colored and how they are mapped from the user’s two- or three-dimensional model space to the two-dimensional screen. There are also calls to effect direct control of the framebuffer, such as reading and writing pixels.

1.5 Implementor’s View of OpenGL

To the implementor, OpenGL is a set of commands that affect the operation of graphics hardware. If the hardware consists only of an addressable framebuffer, then OpenGL must be implemented almost entirely on the host CPU. More typically, the graphics hardware may comprise varying degrees of graphics acceleration, from a raster subsystem capable of rendering two-dimensional lines and polygons to sophisticated floating-point processors capable of transforming and computing on geometric data. The OpenGL implementor’s task is to provide the CPU software interface while dividing the work for each OpenGL command between
the CPU and the graphics hardware. This division must be tailored to the available graphics hardware to obtain optimum performance in carrying out OpenGL calls.

OpenGL maintains a considerable amount of state information. This state controls how objects are drawn into the framebuffer. Some of this state is directly available to the user: he or she can make calls to obtain its value. Some of it, however, is visible only by the effect it has on what is drawn. One of the main goals of this specification is to make OpenGL state information explicit, to elucidate how it changes, and to indicate what its effects are.

1.6 Our View

We view OpenGL as a pipeline having some programmable stages and some state-driven stages that control a set of specific drawing operations. This model should engender a specification that satisfies the needs of both programmers and implementors. It does not, however, necessarily provide a model for implementation. An implementation must produce results conforming to those produced by the specified methods, but there may be ways to carry out a particular computation that are more efficient than the one specified.

1.7 The Deprecation Model

GL features marked as deprecated in one version of the specification are expected to be removed in a future version, allowing applications time to transition away from use of deprecated features. The deprecation model is described in more detail, together with a summary of the commands and state deprecated from this version of the API, in appendix E.

1.8 Companion Documents

1.8.1 OpenGL Shading Language

This specification should be read together with a companion document titled The OpenGL Shading Language. The latter document (referred to as the OpenGL Shading Language Specification hereafter) defines the syntax and semantics of the programming language used to write vertex and fragment shaders (see sections 2.14 and 3.12). These sections may include references to concepts and terms (such as shading language variable types) defined in the companion document.

OpenGL 3.2 implementations are guaranteed to support versions 1.40 and 1.50 (including the compatibility profile of version 1.50) of the OpenGL Shading Lan-
1.8. COMPANION DOCUMENTS

language. All references to sections of that specification refer to version 1.50. The supported version of the shading language may be queried as described in section 6.1.4.

1.8.2 Window System Bindings

OpenGL requires a companion API to create and manage graphics contexts, windows to render into, and other resources beyond the scope of this Specification. There are several such APIs supporting different operating and window systems.

OpenGL Graphics with the X Window System, also called the “GLX Specification”, describes the GLX API for use of OpenGL in the X Window System. It is primarily directed at Linux and Unix systems, but GLX implementations also exist for Microsoft Windows, MacOS X, and some other platforms where X is available. The GLX Specification is available in the OpenGL Extension Registry (see appendix I).

The WGL API supports use of OpenGL with Microsoft Windows. WGL is documented in Microsoft’s MSDN system, although no full specification exists.

Several APIs exist supporting use of OpenGL with Quartz, the MacOS X window system, including CGL, AGL, and NSOpenGLView. These APIs are documented on Apple’s developer website.

The Khronos Native Platform Graphics Interface or “EGL Specification” describes the EGL API for use of OpenGL ES on mobile and embedded devices. EGL implementations may be available supporting OpenGL as well. The EGL Specification is available in the Khronos Extension Registry at URL

http://www.khronos.org/registry/egl
Chapter 2

OpenGL Operation

2.1 OpenGL Fundamentals

OpenGL (henceforth, the “GL”) is concerned only with rendering into a framebuffer (and reading values stored in that framebuffer). There is no support for other peripherals sometimes associated with graphics hardware, such as mice and keyboards. Programmers must rely on other mechanisms to obtain user input.

The GL draws primitives subject to a number of selectable modes and shader programs. Each primitive is a point, line segment, polygon, or pixel rectangle. Each mode may be changed independently; the setting of one does not affect the settings of others (although many modes may interact to determine what eventually ends up in the framebuffer). Modes are set, primitives specified, and other GL operations described by sending commands in the form of function or procedure calls.

Primitives are defined by a group of one or more vertices. A vertex defines a point, an endpoint of an edge, or a corner of a polygon where two edges meet. Data such as positional coordinates, colors, normals, texture coordinates, etc. are associated with a vertex and each vertex is processed independently, in order, and in the same way. The only exception to this rule is if the group of vertices must be clipped so that the indicated primitive fits within a specified region; in this case vertex data may be modified and new vertices created. The type of clipping depends on which primitive the group of vertices represents.

Commands are always processed in the order in which they are received, although there may be an indeterminate delay before the effects of a command are realized. This means, for example, that one primitive must be drawn completely before any subsequent one can affect the framebuffer. It also means that queries and pixel read operations return state consistent with complete execution of all
previously invoked GL commands, except where explicitly specified otherwise. In general, the effects of a GL command on either GL modes or the framebuffer must be complete before any subsequent command can have any such effects.

In the GL, data binding occurs on call. This means that data passed to a command are interpreted when that command is received. Even if the command requires a pointer to data, those data are interpreted when the call is made, and any subsequent changes to the data have no effect on the GL (unless the same pointer is used in a subsequent command).

The GL provides direct control over the fundamental operations of 3D and 2D graphics. This includes specification of parameters of application-defined shader programs performing transformation, lighting, texturing, and shading operations, as well as built-in functionality such as antialiasing and texture filtering. It does not provide a means for describing or modeling complex geometric objects. Another way to describe this situation is to say that the GL provides mechanisms to describe how complex geometric objects are to be rendered rather than mechanisms to describe the complex objects themselves.

The model for interpretation of GL commands is client-server. That is, a program (the client) issues commands, and these commands are interpreted and processed by the GL (the server). The server may or may not operate on the same computer as the client. In this sense, the GL is “network-transparent.” A server may maintain a number of GL contexts, each of which is an encapsulation of current GL state. A client may choose to connect to any one of these contexts. Issuing GL commands when the program is not connected to a context results in undefined behavior.

The GL interacts with two classes of framebuffers: window system-provided and application-created. There is at most one window system-provided framebuffer at any time, referred to as the default framebuffer. Application-created framebuffers, referred to as framebuffer objects, may be created as desired. These two types of framebuffer are distinguished primarily by the interface for configuring and managing their state.

The effects of GL commands on the default framebuffer are ultimately controlled by the window system, which allocates framebuffer resources, determines which portions of the default framebuffer the GL may access at any given time, and communicates to the GL how those portions are structured. Therefore, there are no GL commands to initialize a GL context or configure the default framebuffer. Similarly, display of framebuffer contents on a physical display device (including the transformation of individual framebuffer values by such techniques as gamma correction) is not addressed by the GL.

Allocation and configuration of the default framebuffer occurs outside of the GL in conjunction with the window system, using companion APIs described in...
section 1.8.2.

Allocation and initialization of GL contexts is also done using these companion APIs. GL contexts can typically be associated with different default framebuffers, and some context state is determined at the time this association is performed.

It is possible to use a GL context without a default framebuffer, in which case a framebuffer object must be used to perform all rendering. This is useful for applications needing to perform offscreen rendering.

The GL is designed to be run on a range of graphics platforms with varying graphics capabilities and performance. To accommodate this variety, we specify ideal behavior instead of actual behavior for certain GL operations. In cases where deviation from the ideal is allowed, we also specify the rules that an implementation must obey if it is to approximate the ideal behavior usefully. This allowed variation in GL behavior implies that two distinct GL implementations may not agree pixel for pixel when presented with the same input even when run on identical framebuffer configurations.

Finally, command names, constants, and types are prefixed in the GL (by gl, GL_, and GL, respectively in C) to reduce name clashes with other packages. The prefixes are omitted in this document for clarity.

### 2.1.1 Floating-Point Computation

The GL must perform a number of floating-point operations during the course of its operation. In some cases, the representation and/or precision of such operations is defined or limited; by the OpenGL Shading Language Specification for operations in shaders, and in some cases implicitly limited by the specified format of vertex, texture, or renderbuffer data consumed by the GL. Otherwise, the representation of such floating-point numbers, and the details of how operations on them are performed, is not specified. We require simply that numbers’ floating-point parts contain enough bits and that their exponent fields are large enough so that individual results of floating-point operations are accurate to about 1 part in $10^5$. The maximum representable magnitude of a floating-point number used to represent positional, normal, or texture coordinates must be at least $2^{32}$; the maximum representable magnitude for colors must be at least $2^{10}$. The maximum representable magnitude for all other floating-point values must be at least $2^{32}$. $x \cdot 0 = 0 \cdot x = 0$ for any non-infinite and non-NaN $x$. $1 \cdot x = x \cdot 1 = x$. $x + 0 = 0 + x = x$. $0^0 = 1$. (Occasionally further requirements will be specified.) Most single-precision floating-point formats meet these requirements.

The special values $\text{Inf}$ and $-\text{Inf}$ encode values with magnitudes too large to be represented; the special value $\text{NaN}$ encodes “Not A Number” values resulting from undefined arithmetic operations such as $\frac{1}{0}$. Implementations are permitted,
2.1. OPENGL FUNDAMENTALS

but not required, to support $\infty$s and NaNs in their floating-point computations.

Any representable floating-point value is legal as input to a GL command that requires floating-point data. The result of providing a value that is not a floating-point number to such a command is unspecified, but must not lead to GL interruption or termination. In IEEE arithmetic, for example, providing a negative zero or a denormalized number to a GL command yields predictable results, while providing a NaN or an infinity yields unspecified results.

Some calculations require division. In such cases (including implied divisions required by vector normalizations), a division by zero produces an unspecified result but must not lead to GL interruption or termination.

2.1.2 16-Bit Floating-Point Numbers

A 16-bit floating-point number has a 1-bit sign ($S$), a 5-bit exponent ($E$), and a 10-bit mantissa ($M$). The value $V$ of a 16-bit floating-point number is determined by the following:

$$V = \begin{cases} 
(-1)^S \times 0.0, & E = 0, M = 0 \\
(-1)^S \times 2^{-14} \times \frac{M}{2^{10}}, & E = 0, M \neq 0 \\
(-1)^S \times 2^{E-15} \times (1 + \frac{M}{2^{10}}), & 0 < E < 31 \\
(-1)^S \times \infty, & E = 31, M = 0 \\
NaN, & E = 31, M \neq 0 
\end{cases}$$

If the floating-point number is interpreted as an unsigned 16-bit integer $N$, then

$$S = \left\lfloor \frac{N \mod 65536}{32768} \right\rfloor$$

$$E = \left\lfloor \frac{N \mod 32768}{1024} \right\rfloor$$

$$M = N \mod 1024.$$

Any representable 16-bit floating-point value is legal as input to a GL command that accepts 16-bit floating-point data. The result of providing a value that is not a floating-point number (such as $\infty$ or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number or negative zero to GL must yield predictable results.
2.1.3 Unsigned 11-Bit Floating-Point Numbers

An unsigned 11-bit floating-point number has no sign bit, a 5-bit exponent \((E)\), and a 6-bit mantissa \((M)\). The value \(V\) of an unsigned 11-bit floating-point number is determined by the following:

\[
V = \begin{cases} 
0.0, & E = 0, M = 0 \\
2^{-14} \times \frac{M}{64}, & E = 0, M \neq 0 \\
2^{E-15} \times (1 + \frac{M}{64}), & 0 < E < 31 \\
\text{Inf}, & E = 31, M = 0 \\
\text{NaN}, & E = 31, M \neq 0 
\end{cases}
\]

If the floating-point number is interpreted as an unsigned 11-bit integer \(N\), then

\[
E = \left\lfloor \frac{N}{64} \right\rfloor \\
M = N \mod 64.
\]

When a floating-point value is converted to an unsigned 11-bit floating-point representation, finite values are rounded to the closest representable finite value. While less accurate, implementations are allowed to always round in the direction of zero. This means negative values are converted to zero. Likewise, finite positive values greater than 65024 (the maximum finite representable unsigned 11-bit floating-point value) are converted to 65024. Additionally: negative infinity is converted to zero; positive infinity is converted to positive infinity; and both positive and negative NaN are converted to positive NaN.

Any representable unsigned 11-bit floating-point value is legal as input to a GL command that accepts 11-bit floating-point data. The result of providing a value that is not a floating-point number (such as Inf or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number to GL must yield predictable results.

2.1.4 Unsigned 10-Bit Floating-Point Numbers

An unsigned 10-bit floating-point number has no sign bit, a 5-bit exponent \((E)\), and a 5-bit mantissa \((M)\). The value \(V\) of an unsigned 10-bit floating-point number is determined by the following:
2.1. OPENGL FUNDAMENTALS

\[ V = \begin{cases} 
0.0, & E = 0, M = 0 \\
2^{-14} \times \frac{M}{32}, & E = 0, M \neq 0 \\
2^{E-15} \times (1 + \frac{M}{32}), & 0 < E < 31 \\
\text{Inf}, & E = 31, M = 0 \\
\text{NaN}, & E = 31, M \neq 0 
\end{cases} \]

If the floating-point number is interpreted as an unsigned 10-bit integer \( N \), then

\[ E = \left\lfloor \frac{N}{32} \right\rfloor \]
\[ M = N \mod 32. \]

When a floating-point value is converted to an unsigned 10-bit floating-point representation, finite values are rounded to the closest representable finite value. While less accurate, implementations are allowed to always round in the direction of zero. This means negative values are converted to zero. Likewise, finite positive values greater than 64512 (the maximum finite representable unsigned 10-bit floating-point value) are converted to 64512. Additionally: negative infinity is converted to zero; positive infinity is converted to positive infinity; and both positive and negative NaN are converted to positive NaN.

Any representable unsigned 10-bit floating-point value is legal as input to a GL command that accepts 10-bit floating-point data. The result of providing a value that is not a floating-point number (such as Inf or NaN) to such a command is unspecified, but must not lead to GL interruption or termination. Providing a denormalized number to GL must yield predictable results.

2.1.5 Fixed-Point Data Conversions

When generic vertex attributes and pixel color or depth components are represented as integers, they are often (but not always) considered to be normalized. Normalized integer values are treated specially when being converted to and from floating-point values, and are usually referred to as normalized fixed-point. Such values are always either signed or unsigned.

In the remainder of this section, \( b \) denotes the bit width of the fixed-point integer representation. When the integer is one of the types defined in table 2.2, \( b \) is the minimum required bit width of that type. When the integer is a texture or renderbuffer color or depth component (see section 3.9.1), \( b \) is the number of bits allocated to that component in the internal format of the texture or renderbuffer.
When the integer is a framebuffer color or depth component (see section 4), \( b \) is the number of bits allocated to that component in the framebuffer. For framebuffer and renderbuffer A components, \( b \) must be at least 2 if the buffer does not contain an A component, or if there is only 1 bit of A in the buffer.

The signed and unsigned fixed-point representations are assumed to be \( b \)-bit binary twos-complement integers and binary unsigned integers, respectively. The signed fixed-point representation may be treated in one of two ways, as discussed below.

All the conversions described below are performed as defined, even if the implemented range of an integer data type is greater than the minimum required range.

**Conversion from Normalized Fixed-Point to Floating-Point**

Unsigned normalized fixed-point integers represent numbers in the range \([0, 1]\). The conversion from an unsigned normalized fixed-point value \( c \) to the corresponding floating-point value \( f \) is defined as

\[
    f = \frac{c}{2^b - 1}.
\]  

(2.1)

Signed normalized fixed-point integers represent numbers in the range \([-1, 1]\). The conversion from a signed normalized fixed-point value \( c \) to the corresponding floating-point value \( f \) may be performed in two ways:

\[
    f = \frac{2c + 1}{2^b - 1}
\]  

(2.2)

In this case the full range of the representation is used, so that \(-2^{b-1}\) corresponds to -1.0 and \(2^{b-1} - 1\) corresponds to 1.0. For example, if \( b = 8 \), then the integer value -128 corresponds to -1.0 and the value 127 corresponds to 1.0. Note that it is not possible to exactly express 0 in this representation. In general, this representation is used for signed normalized fixed-point parameters in GL commands, such as vertex attribute values.

Alternatively, conversion may be performed using

\[
    f = \max \left\{ \frac{c}{2^{b-1} - 1}, -1.0 \right\}.
\]  

(2.3)

In this case only the range \([-2^{b-1} + 1, 2^{b-1} - 1]\) is used to represent signed fixed-point values in the range \([-1, 1]\). For example, if \( b = 8 \), then the integer value -127 corresponds to -1.0 and the value 127 corresponds to 1.0. Note that while zero can be exactly expressed in this representation, one value (-128 in the example) is outside the representable range, and must be clamped before use.
2.2. *GL STATE*

general, this representation is used for signed normalized fixed-point texture or framebuffer values.

Everywhere that signed normalized fixed-point values are converted, the equation used is specified.

**Conversion from Floating-Point to Normalized Fixed-Point**

The conversion from a floating-point value $f$ to the corresponding unsigned normalized fixed-point value $c$ is defined by first clamping $f$ to the range $[0, 1]$, then computing

$$
f' = f \times (2^b - 1). \quad (2.4)
$$

$f'$ is then cast to an unsigned binary integer value with exactly $b$ bits.

The conversion from a floating-point value $f$ to the corresponding signed normalized fixed-point value $c$ may be performed in two ways, both beginning by clamping $f$ to the range $[-1, 1]$:  

$$
f' = \frac{f \times (2^b - 1) - 1}{2} \quad (2.5)
$$

In general, this conversion is used when querying floating-point state (see section 6) and returning integers.

Alternatively, conversion may be performed using

$$
f' = f \times (2^{b-1} - 1). \quad (2.6)
$$

In general, this conversion is used when specifying signed normalized fixed-point texture or framebuffer values.

After conversion, $f'$ is then cast to a signed two’s-complement binary integer value with exactly $b$ bits.

Everywhere that floating-point values are converted to signed normalized fixed-point, the equation used is specified.

2.2 GL State

The GL maintains considerable state. This document enumerates each state variable and describes how each variable can be changed. For purposes of discussion, state variables are categorized somewhat arbitrarily by their function. Although we describe the operations that the GL performs on the framebuffer, the framebuffer is not a part of GL state.
2.3. **GL COMMAND SYNTAX**

We distinguish two types of state. The first type of state, called GL *server state*, resides in the GL server. The majority of GL state falls into this category. The second type of state, called GL *client state*, resides in the GL client. Unless otherwise specified, all state referred to in this document is GL server state; GL client state is specifically identified. Each instance of a GL context implies one complete set of GL server state; each connection from a client to a server implies a set of both GL client state and GL server state.

While an implementation of the GL may be hardware dependent, this discussion is independent of the specific hardware on which a GL is implemented. We are therefore concerned with the state of graphics hardware only when it corresponds precisely to GL state.

### 2.2.1 Shared Object State

It is possible for groups of contexts to share certain state. Enabling such sharing between contexts is done through window system binding APIs such as those described in section 1.8.2. These APIs are responsible for creation and management of contexts, and not discussed further here. More detailed discussion of the behavior of shared objects is included in appendix D. Except as defined in this appendix, all state in a context is specific to that context only.

### 2.3 GL Command Syntax

GL commands are functions or procedures. Various groups of commands perform the same operation but differ in how arguments are supplied to them. To conveniently accommodate this variation, we adopt a notation for describing commands and their arguments.

GL commands are formed from a *name* which may be followed, depending on the particular command, by a sequence of characters describing a parameter to the command. If present, a digit indicates the required length (number of values) of the indicated type. Next, a string of characters making up one of the *type descriptors* from table 2.1 indicates the specific size and data type of parameter values. A final v character, if present, indicates that the command takes a pointer to an array (a vector) of values rather than a series of individual arguments. Two specific examples are:

```c
void Uniform4f( int location, float v0, float v1,
float v2, float v3 );
```

and

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.3. GL COMMAND SYNTAX

<table>
<thead>

<td>float</td>
</tr>
<tr>
<td>d</td>
<td>double</td>
</tr>
<tr>
<td>ub</td>
<td>ubyte</td>
</tr>
<tr>
<td>us</td>
<td>ushort</td>
</tr>
<tr>
<td>ui</td>
<td>uint</td>
</tr>
</tbody>
</table>

Table 2.1: Correspondence of command suffix type descriptors to GL argument types. Refer to table 2.2 for definitions of the GL types.

```c
void GetFloatv( enum value, float *data );
```

These examples show the ANSI C declarations for these commands. In general, a command declaration has the form:\footnote{The declarations shown in this document apply to ANSI C. Languages such as C++ and Ada that allow passing of argument type information admit simpler declarations and fewer entry points.}

```c
rtype Name{ε1234}{ε b s i i64 f d ub us ui}{εv}
( [args ,] T arg1 , . . . , T argN [, args] ) ;
```

`rtype` is the return type of the function. The braces (`{ }`) enclose a series of type descriptors (see table 2.1), of which one is selected. `ε` indicates no type descriptor. The arguments enclosed in brackets (`[args ,]` and `[ , args]`) may or may not be present. The `N` arguments `arg1` through `argN` have type `T`, which corresponds to one of the type descriptors indicated in table 2.1 (if there are no letters, then the arguments’ type is given explicitly). If the final character is not `v`, then `N` is given by the digit `1, 2, 3,` or `4` (if there is no digit, then the number of arguments is fixed). If the final character is `v`, then only `arg1` is present and it is an array of `N` values of the indicated type.

For example,

```c
void Uniform{1234}{if}( int location, T value );
```

indicates the eight declarations

```c
void Uniform1i( int location, int value );
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
void Uniform1f(int location, float value);
void Uniform2i(int location, int v0, int v1);
void Uniform2f(int location, float v0, float v1);
void Uniform3i(int location, int v0, int v1, int v2);
void Uniform3f(int location, float v1, float v2, float v3);
void Uniform4i(int location, int v0, int v1, int v2, int v3);
void Uniform4f(int location, float v0, float v1, float v2, float v3);

Arguments whose type is fixed (i.e. not indicated by a suffix on the command) are of one of the GL data types summarized in table 2.2, or pointers to one of these types.

2.4 Basic GL Operation

Figure 2.1 shows a schematic diagram of the GL. Commands enter the GL on the left. Some commands specify geometric objects to be drawn while others control how the objects are handled by the various stages. Most commands may be accumulated in a display list for processing by the GL at a later time. Otherwise, commands are effectively sent through a processing pipeline.

The first stage provides an efficient means for approximating curve and surface geometry by evaluating polynomial functions of input values. It operates on geometric primitives described by vertices: points, line segments, and polygons. In this stage vertices are transformed and lit, followed by assembly into geometric primitives, which may optionally be used by the next stage, geometry shading, to generate new primitives. The final resulting primitives are clipped to a viewing volume in preparation for the next stage, rasterization. The rasterizer produces a series of framebuffer addresses and values using a two-dimensional description of a point, line segment, or polygon. Each fragment so produced is fed to the next stage that performs operations on individual fragments before they finally alter the framebuffer. These operations include conditional updates into the framebuffer based on incoming and previously stored depth values (to effect depth buffering), blending of incoming fragment colors with stored colors, as well as masking and other logical operations on fragment values.

Finally, there is a way to bypass the vertex processing portion of the pipeline to send a block of fragments directly to the individual fragment operations, eventually causing a block of pixels to be written to the framebuffer; values may also be read...

Table 2.2: GL data types. GL types are not C types. Thus, for example, GL type `int` is referred to as `GLint` outside this document, and is not necessarily equivalent to the C type `int`. An implementation may use more bits than the number indicated in the table to represent a GL type. Correct interpretation of integer values outside the minimum range is not required, however.

`ptrbits` is the number of bits required to represent a pointer type; in other words, types `intptr`, `sizeiptr`, and `sync` must be sufficiently large as to store any address.
2.5. GL ERRORS

The GL detects only a subset of those conditions that could be considered errors. This is because in many cases error checking would adversely impact the performance of an error-free program.

The command

```c
enum GetError(void);
```

is used to obtain error information. Each detectable error is assigned a numeric code. When an error is detected, a flag is set and the code is recorded. Further errors, if they occur, do not affect this recorded code. When `GetError` is called, the code is returned and the flag is cleared, so that a further error will again record its code. If a call to `GetError` returns `NO_ERROR`, then there has been no detectable error since the last call to `GetError` (or since the GL was initialized).
To allow for distributed implementations, there may be several flag-code pairs. In this case, after a call to `GetError` returns a value other than `NO_ERROR` each subsequent call returns the non-zero code of a distinct flag-code pair (in unspecified order), until all non-`NO_ERROR` codes have been returned. When there are no more non-`NO_ERROR` error codes, all flags are reset. This scheme requires some positive number of pairs of a flag bit and an integer. The initial state of all flags is cleared and the initial value of all codes is `NO_ERROR`.

Table 2.3 summarizes GL errors. Currently, when an error flag is set, results of GL operation are undefined only if `OUT_OF_MEMORY` has occurred. In other cases, the command generating the error is ignored so that it has no effect on GL state or framebuffer contents. If the generating command returns a value, it returns zero. If the generating command modifies values through a pointer argument, no change is made to these values. These error semantics apply only to GL errors, not to system errors such as memory access errors. This behavior is the current behavior; the action of the GL in the presence of errors is subject to change.

Several error generation conditions are implicit in the description of every GL command:

- If a command that requires an enumerated value is passed a symbolic constant that is not one of those specified as allowable for that command, the error `INVALID_ENUM` is generated. This is the case even if the argument is a pointer to a symbolic constant, if the value pointed to is not allowable for the given command.
- If a negative number is provided where an argument of type `sizei` or `sizeiptr` is specified, the error `INVALID_VALUE` is generated.
- If memory is exhausted as a side effect of the execution of a command, the error `OUT_OF_MEMORY` may be generated.

Otherwise, errors are generated only for conditions that are explicitly described in this specification.

## 2.6 Begin/End Paradigm

In the GL, most geometric objects are drawn by enclosing a series of coordinate sets that specify vertices and optionally normals, texture coordinates, and colors between `Begin/End` pairs. Points, lines, polygons, and a variety of related geometric objects (see section 2.6.1) can be drawn in this way.

Each vertex is specified with two, three, or four coordinates. In addition, a `current normal`, multiple `current texture coordinate sets`, multiple `current generic`

Table 2.3: Summary of GL errors

*vertex attributes, current color, current secondary color,* and *current fog coordinate* may be used in processing each vertex. Normals are used by the GL in lighting calculations; the current normal is a three-dimensional vector that may be set by sending three coordinates that specify it. Texture coordinates determine how a texture image is mapped onto a primitive. Multiple sets of texture coordinates may be used to specify how multiple texture images are mapped onto a primitive. The number of texture units supported is implementation-dependent but must be at least two. The number of texture units supported can be queried with the state `MAX_TEXTURE_UNITS`. Generic vertex attributes can be accessed from within vertex shaders (section 2.14) and used to compute values for consumption by later processing stages.

Primary and secondary colors are associated with each vertex (see section 3.10). These *associated* colors are either based on the current color and current secondary color or produced by lighting, depending on whether or not lighting is enabled. Texture and fog coordinates are similarly associated with each vertex. Multiple sets of texture coordinates may be associated with a vertex. Figure 2.2 summarizes the association of auxiliary data with a transformed vertex to produce a *processed vertex*.

The current values are part of GL state. Vertices and normals are transformed, colors may be affected or replaced by lighting, and texture coordinates are transformed and possibly affected by a texture coordinate generation function. The
Figure 2.2. Association of current values with a vertex. The heavy lined boxes represent GL state. Four texture units are shown; however, multitexturing may support a different number of units depending on the implementation.
processing indicated for each current value is applied for each vertex that is sent to the GL.

The methods by which vertices, normals, texture coordinates, fog coordinate, generic attributes, and colors are sent to the GL, as well as how normals are transformed and how vertices are mapped to the two-dimensional screen, are discussed later.

Before colors have been assigned to a vertex, the state required by a vertex is the vertex’s coordinates, the current normal, the current edge flag (see section 2.6.2), the current material properties (see section 2.13.2), the current fog coordinate, the multiple generic vertex attribute sets, and the multiple current texture coordinate sets. Because color assignment is done vertex-by-vertex, a processed vertex comprises the vertex’s coordinates, its edge flag, its fog coordinate, its assigned colors, and its multiple texture coordinate sets.

Figure 2.3 shows the sequence of operations that builds a *primitive* (point, line segment, or polygon) from a sequence of vertices. After a primitive is formed, it is clipped to a viewing volume. This may alter the primitive by altering vertex coordinates, texture coordinates, and colors. In the case of line and polygon primitives, clipping may insert new vertices into the primitive. The vertices defining a primitive to be rasterized have texture coordinates and colors associated with them.
2.6. BEGIN/END PARADIGM

2.6.1 Begin and End

Vertices making up one of the supported geometric object types are specified by enclosing commands defining those vertices between the two commands

```
void Begin(enum mode);
void End(void);
```

There is no limit on the number of vertices that may be specified between a Begin and an End. The mode parameter of Begin determines the type of primitives to be drawn using the vertices. The types, and the corresponding mode parameters, are:

Points
A series of individual points may be specified with mode POINTS. Each vertex defines a separate point. No special state need be kept between Begin and End in this case, since each point is independent of previous and following points.

Line Strips
A series of one or more connected line segments may be specified with mode LINE_STRIP. In this case, the first vertex specifies the first segment’s start point while the second vertex specifies the first segment’s endpoint and the second segment’s start point. In general, the ith vertex (for i > 1) specifies the beginning of the ith segment and the end of the i − 1st. The last vertex specifies the end of the last segment. If only one vertex is specified, then no primitive is generated.

The required state consists of the processed vertex produced from the last vertex that was sent (so that a line segment can be generated from it to the current vertex), and a boolean flag indicating if the current vertex is the first vertex.

Line Loops
Line loops may be specified with mode LINE_LOOP. Loops are the same as line strips except that a final segment is added from the final specified vertex to the first vertex. The required state consists of the processed first vertex, in addition to the state required for line strips.

Separate Lines
Individual line segments, each specified by a pair of vertices, may be specified with mode LINES. The first two vertices between a Begin and End pair define the first segment, with subsequent pairs of vertices each defining one more segment. If the number of specified vertices is odd, then the last one is ignored. The state required is the same as for line strips but it is used differently: a processed vertex holding the first vertex of the current segment, and a boolean flag indicating whether the current vertex is odd or even (a segment start or end).
2.6. BEGIN/END PARADIGM

Polygons

A polygon is described by specifying its boundary as a series of line segments. When `Begin` is called with `POLYGON`, the bounding line segments are specified in the same way as line loops. A polygon described with fewer than three vertices does not generate a primitive.

The state required to support polygons consists of at least two processed vertices (more than two are never required, although an implementation may use more); this is because a convex polygon can be rasterized as its vertices arrive, before all of them have been specified.

Triangle Strips

A triangle strip is a series of triangles connected along shared edges, and may be specified with `mode TRIANGLE_STRIP`. In this case, the first three vertices define the first triangle (and their order is significant, just as for polygons). Each subsequent vertex defines a new triangle using that point along with two vertices from the previous triangle. If fewer than three vertices are specified, no primitive is produced. See figure 2.4.

The required state consists of a flag indicating if the first triangle has been completed, two stored processed vertices, (called vertex A and vertex B), and a one bit pointer indicating which stored vertex will be replaced with the next vertex. After `Begin( TRIANGLE_STRIP )`, the pointer is initialized to point to vertex A. Each successive vertex toggles the pointer. Therefore, the first vertex is stored as

Figure 2.4. (a) A triangle strip. (b) A triangle fan. (c) Independent triangles. The numbers give the sequencing of the vertices in order within the vertex arrays. Note that in (a) and (b) triangle edge ordering is determined by the first triangle, while in (c) the order of each triangle’s edges is independent of the other triangles.
2.6. BEGIN/END PARADIGM

vertex A, the second stored as vertex B, the third stored as vertex A, and so on. Any vertex after the second one sent forms a triangle from vertex A, vertex B, and the current vertex (in that order).

**Triangle Fans**

A triangle fan is the same as a triangle strip with one exception: each vertex after the first always replaces vertex B of the two stored vertices. A triangle fan may be specified with mode TRIANGLE_FAN.

**Separate Triangles**

Separate triangles are specified with mode TRIANGLES. In this case, The $3i + 1$st, $3i + 2$nd, and $3i + 3$rd vertices (in that order) determine a triangle for each $i = 0, 1, \ldots, n - 1$, where there are $3n + k$ vertices drawn. $k$ is either 0, 1, or 2; if $k$ is not zero, the final $k$ vertices are ignored. For each triangle, vertex A is vertex $3i$ and vertex B is vertex $3i + 1$. Otherwise, separate triangles are the same as a triangle strip.

**Quadrilateral (quad) strips**

Quad strips generate a series of edge-sharing quadrilaterals from vertices appearing between Begin and End, when Begin is called with QUAD_STRIP. If the $m$ vertices between the Begin and End are $v_1, \ldots, v_m$, where $v_j$ is the $j$th specified vertex, then quad $i$ has vertices (in order) $v_{2i}$, $v_{2i+1}$, $v_{2i+3}$, and $v_{2i+2}$ with $i = 0, \ldots, \lfloor m/2 \rfloor$. The state required is thus three processed vertices, to store the last two vertices of the previous quad along with the third vertex (the first new vertex) of the current quad, a flag to indicate when the first quad has been completed, and a one-bit counter to count members of a vertex pair. See figure 2.5.

A quad strip with fewer than four vertices generates no primitive. If the number of vertices specified for a quadrilateral strip between Begin and End is odd, the final vertex is ignored.

**Separate Quadrilaterals**

Separate quads are just like quad strips except that each group of four vertices, the $4j + 1$st, the $4j + 2$nd, the $4j + 3$rd, and the $4j + 4$th, generate a single quad, for $j = 0, 1, \ldots, n - 1$. The total number of vertices between Begin and End is $4n + k$, where $0 \leq k \leq 3$; if $k$ is not zero, the final $k$ vertices are ignored. Separate quads are generated by calling Begin with the argument value QUADS.

**Lines with Adjacency**

Lines with adjacency are independent line segments where each endpoint has a corresponding adjacent vertex that can be accessed by a geometry shader (sec-
2.6. BEGIN/END PARADIGM

Figure 2.5. (a) A quad strip. (b) Independent quads. The numbers give the sequencing of the vertices between Begin and End.

If a geometry shader is not active, the adjacent vertices are ignored. They are generated with mode `LINES_ADJACENCY`.

A line segment is drawn from the \(4i + 2\)nd vertex to the \(4i + 3\)rd vertex for each \(i = 0, 1, \ldots, n - 1\), where there are \(4n + k\) vertices between a Begin and End pair. \(k\) is either 0, 1, 2, or 3; if \(k\) is not zero, the final \(k\) vertices are ignored. For line segment \(i\), the \(4i + 1\)st and \(4i + 4\)th vertices are considered adjacent to the \(4i + 2\)nd and \(4i + 3\)rd vertices, respectively (see figure 2.6).

**Line Strips with Adjacency**

Line strips with adjacency are similar to line strips, except that each line segment has a pair of adjacent vertices that can be accessed by a geometry shader. If a geometry shader is not active, the adjacent vertices are ignored. They are generated with mode `LINE_STRIP_ADJACENCY`.

A line segment is drawn from the \(i + 2\)nd vertex to the \(i + 3\)rd vertex for each \(i = 0, 1, \ldots, n - 1\), where there are \(n + 3\) vertices between a Begin and End pair. If there are fewer than four vertices, all vertices are ignored. For line segment \(i\), the \(i + 1\)st and \(i + 4\)th vertex are considered adjacent to the \(i + 2\)nd and \(i + 3\)rd vertices, respectively (see figure 2.6).

**Triangles with Adjacency**

Triangles with adjacency are similar to separate triangles, except that each triangle edge has an adjacent vertex that can be accessed by a geometry shader. If a geometry shader is not active, the adjacent vertices are ignored. They are generated with mode `TRIANGLES_ADJACENCY`.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.6. BEGIN/END PARADIGM

Figure 2.6. Lines with adjacency (a) and line strips with adjacency (b). The vertices connected with solid lines belong to the main primitives; the vertices connected by dashed lines are the adjacent vertices that may be used in a geometry shader.

Figure 2.7. Triangles with adjacency. The vertices connected with solid lines belong to the main primitive; the vertices connected by dashed lines are the adjacent vertices that may be used in a geometry shader.
The $6i + 1$st, $6i + 3$rd, and $6i + 5$th vertices (in that order) determine a triangle for each $i = 0, 1, \ldots, n - 1$, where there are $6n + k$ vertices between a Begin and End pair. $k$ is either 0, 1, 2, 3, 4, or 5; if $k$ is non-zero, the final $k$ vertices are ignored. For triangle $i$, the $i + 2$nd, $i + 4$th, and $i + 6$th vertices are considered adjacent to edges from the $i + 1$st to the $i + 3$rd, from the $i + 3$rd to the $i + 5$th, and from the $i + 5$th to the $i + 1$st vertices, respectively (see figure 2.7).

**Triangle Strips with Adjacency**

Triangle strips with adjacency are similar to triangle strips, except that each line triangle edge has an adjacent vertex that can be accessed by a geometry shader. If a geometry shader is not active, the adjacent vertices are ignored. They are generated with mode `TRIANGLE_STRIP_ADJACENCY`.

In triangle strips with adjacency, $n$ triangles are drawn where there are $2(n + 2) + k$ vertices between a Begin and End pair. $k$ is either 0 or 1; if $k$ is 1, the final vertex is ignored. If there are fewer than 6 vertices, the entire primitive is ignored. Table 2.4 describes the vertices and order used to draw each triangle, and which vertices are considered adjacent to each edge of the triangle (see figure 2.8).

Depending on the current state of the GL, a polygon primitive generated from a drawing command with mode `POLYGON`, `QUADS`, `QUAD_STRIP`, `TRIANGLE_FAN`, `TRIANGLE_STRIP`, `TRIANGLES`, `TRIANGLES_ADJACENCY`, or `TRIANGLE_STRIP_ADJACENCY` may be rendered in one of several ways, such as outlining its border or filling its interior. The order of vertices in such a prim-
Table 2.4: Triangles generated by triangle strips with adjacency. Each triangle is drawn using the vertices whose numbers are in the 1st, 2nd, and 3rd columns under *primitive vertices*, in that order. The vertices in the 1/2, 2/3, and 3/1 columns under *adjacent vertices* are considered adjacent to the edges from the first to the second, from the second to the third, and from the third to the first vertex of the triangle, respectively. The six rows correspond to six cases: the first and only triangle \((i = 0, n = 1)\), the first triangle of several \((i = 0, n > 0)\), “odd” middle triangles \((i = 1, 3, 5 \ldots)\), “even” middle triangles \((i = 2, 4, 6, \ldots)\), and special cases for the last triangle, when \(i\) is either even or odd. For the purposes of this table, the first vertex specified after *Begin* is numbered 1 and the first triangle is numbered 0.
2.6. BEGIN/END PARADIGM

Positive is significant in lighting, polygon rasterization, and fragment shading (see sections 2.13.1, 3.6.1, and 3.12.2). Only convex polygons are guaranteed to be drawn correctly by the GL. If a specified polygon is nonconvex when projected onto the window, then the rendered polygon need only lie within the convex hull of the projected vertices defining its boundary.

The state required for Begin and End consists of an fifteen-valued integer indicating either one of the fourteen possible Begin/End modes, or that no Begin/End mode is being processed.

Calling Begin will result in an INVALID_FRAMEBUFFER_OPERATION error if the object bound to DRAW_FRAMEBUFFER_BINDING is not framebuffer complete (see section 4.4.4).

2.6.2 Polygon Edges

Each edge of each polygon primitive generated is flagged as either boundary or non-boundary. These classifications are used during polygon rasterization; some modes affect the interpretation of polygon boundary edges (see section 3.6.4). By default, all edges are boundary edges, but the flagging of polygons, separate triangles, or separate quadrilaterals may be altered by calling

```c
void EdgeFlag(boolean flag);
void EdgeFlagv(boolean *flag);
```

to change the value of a flag bit. If flag is zero, then the flag bit is set to FALSE; if flag is non-zero, then the flag bit is set to TRUE.

When Begin is supplied with one of the argument values POLYGON, TRIANGLES, or QUADS, each vertex specified within a Begin and End pair begins an edge. If the edge flag bit is TRUE, then each specified vertex begins an edge that is flagged as boundary. If the bit is FALSE, then induced edges are flagged as non-boundary.

The state required for edge flagging consists of one current flag bit. Initially, the bit is TRUE. In addition, each processed vertex of an assembled polygonal primitive must be augmented with a bit indicating whether or not the edge beginning on that vertex is boundary or non-boundary.

2.6.3 GL Commands within Begin/End

The only GL commands that are allowed within any Begin/End pairs are the commands for specifying vertex coordinates, vertex colors, normal coordinates, texture coordinates, generic vertex attributes, and fog coordinates (Vertex, Color, SecondaryColor, Index, Normal, TexCoord and MultiTexCoord, VertexAttrib,
2.7. VERTEX SPECIFICATION

FogCoord), the ArrayElement command (see section 2.8), the EvalCoord and EvalPoint commands (see section 5.1), commands for specifying lighting material parameters (Material commands; see section 2.13.2), display list invocation commands (CallList and CallLists; see section 5.4), and the EdgeFlag command. Executing any other GL command between the execution of Begin and the corresponding execution of End results in the error INVALID_OPERATION. Executing Begin after Begin has already been executed but before an End is executed generates the INVALID_OPERATION error, as does executing End without a previous corresponding Begin.

Execution of the commands EnableClientState, DisableClientState, PushClientAttrib, PopClientAttrib, ColorPointer, FogCoordPointer, EdgeFlagPointer, IndexPointer, NormalPointer, TexCoordPointer, SecondaryColorPointer, VertexPointer, VertexAttribPointer, ClientActiveTexture, InterleavedArrays, and PixelStore is not allowed within any Begin/End pair, but an error may or may not be generated if such execution occurs. If an error is not generated, GL operation is undefined. (These commands are described in sections 2.8, 3.7.1, and chapter 6.)

2.7 Vertex Specification

Vertices are specified by giving their coordinates in two, three, or four dimensions. This is done using one of several versions of the Vertex command:

```c
void Vertex{234}{sifd}({ T coords });
void Vertex{234}{sifd}v({ T coords });
```

A call to any Vertex command specifies four coordinates: $x$, $y$, $z$, and $w$. The $x$ coordinate is the first coordinate, $y$ is second, $z$ is third, and $w$ is fourth. A call to Vertex2 sets the $x$ and $y$ coordinates; the $z$ coordinate is implicitly set to zero and the $w$ coordinate to one. Vertex3 sets $x$, $y$, and $z$ to the provided values and $w$ to one. Vertex4 sets all four coordinates, allowing the specification of an arbitrary point in projective three-space. Invoking a Vertex command outside of a Begin/End pair results in undefined behavior.

Current values are used in associating auxiliary data with a vertex as described in section 2.5. A current value may be changed at any time by issuing an appropriate command. The commands

```c
void TexCoord{1234}{sifd}({ T coords });
void TexCoord{1234}{sifd}v({ T coords });
```
specify the current homogeneous texture coordinates, named \( s, t, r, \) and \( q \). The \texttt{TexCoord1} family of commands set the \( s \) coordinate to the provided single argument while setting \( t \) and \( r \) to 0 and \( q \) to 1. Similarly, \texttt{TexCoord2} sets \( s \) and \( t \) to the specified values, \( r \) to 0 and \( q \) to 1; \texttt{TexCoord3} sets \( s, t, \) and \( r \), with \( q \) set to 1, and \texttt{TexCoord4} sets all four texture coordinates.

Implementations must support at least two sets of texture coordinates. The commands

\begin{verbatim}
void MultiTexCoord{1234}{sifd}(enum texture, T coords)
void MultiTexCoord{1234}{sifd}v(enum texture, T coords)
\end{verbatim}

take the coordinate set to be modified as the \textit{texture} parameter. \textit{Texture} is a symbolic constant of the form \texttt{TEXTURE}i, indicating that texture coordinate set \( i \) is to be modified. The constants obey \texttt{TEXTURE}i = \texttt{TEXTURE0} + \( i \) (\( i \) is in the range 0 to \( k - 1 \), where \( k \) is the implementation-dependent number of texture coordinate sets defined by \texttt{MAX_TEXTURE_COORDS}).

The \texttt{TexCoord} commands are exactly equivalent to the corresponding \texttt{MultiTexCoord} commands with \textit{texture} set to \texttt{TEXTURE0}.

\textit{Gets} of \texttt{CURRENT_TEXTURE_COORDS} return the texture coordinate set defined by the value of \texttt{ACTIVE_TEXTURING}.

Specifying an invalid texture coordinate set for the \textit{texture} argument of \texttt{MultiTexCoord} results in undefined behavior.

The current normal is set using

\begin{verbatim}
void Normal3{bsifd}( T coords);
void Normal3{bsifd}v( T coords);
\end{verbatim}

Byte, short, or integer values passed to \texttt{Normal} are converted to floating-point values as described in equation 2.2 for the corresponding (signed) type.

The current fog coordinate is set using

\begin{verbatim}
void FogCoord{fd}( T coord);
void FogCoord{fd}v( T coord);
\end{verbatim}

There are several ways to set the current color and secondary color. The GL stores a current single-valued \textit{color index}, as well as a current four-valued RGBA color and secondary color. Either the index or the color and secondary color are significant depending as the GL is in \textit{color index mode} or \textit{RGBA mode}. The mode selection is made when the GL is initialized.

The commands to set RGBA colors are
2.7 VERTEX SPECIFICATION

void Color{34}{bsifd ubusui}( T components );
void Color{34}{bsifd ubusui}v( T components );
void SecondaryColor3{bsifd ubusui}( T components );
void SecondaryColor3{bsifd ubusui}v( T components );

The Color command has two major variants: Color3 and Color4. The four value versions set all four values. The three value versions set R, G, and B to the provided values; A is set to 1.0. (The conversion of integer color components (R, G, B, and A) to floating-point values is discussed in section 2.13.)

The secondary color has only the three value versions. Secondary A is always set to 1.0.

Versions of the Color and SecondaryColor commands that take floating-point values accept values nominally between 0.0 and 1.0. 0.0 corresponds to the minimum while 1.0 corresponds to the maximum (machine dependent) value that a component may take on in the framebuffer (see section 2.13 on colors and coloring). Values outside [0, 1] are not clamped.

The command

void Index{si fd ub}( T index );
void Index{si fd ub}v( T index );

updates the current (single-valued) color index. It takes one argument, the value to which the current color index should be set. Values outside the (machine-dependent) representable range of color indices are not clamped.

Vertex shaders (see section 2.14) can be written to access an array of 4-component generic vertex attributes in addition to the conventional attributes specified previously. The first slot of this array is numbered 0, and the size of the array is specified by the implementation-dependent constant MAX_VERTEX_ATTRIBS.

Current generic attribute values define generic attributes for a vertex. The current values of a generic shader attribute declared as a floating-point scalar, vector, or matrix may be changed at any time by issuing one of the commands

void VertexAttrib{1234}{sfd}( uint index, T values );
void VertexAttrib{123}{sfd}v( uint index, T values );
void VertexAttrib4{bsifd ub us ui}v( uint index, T values );
void VertexAttrib4Nub( uint index, T values );
void VertexAttrib4N{bsi ub us ui}v( uint index, T values );

The VertexAttrib4N* commands specify fixed-point values that are converted to a normalized [0, 1] or [-1, 1] range as described in equations 2.1 and 2.2, respectively, while the other commands specify values that are converted directly to the internal floating-point representation.
The resulting value(s) are loaded into the generic attribute at slot *index*, whose components are named \(x\), \(y\), \(z\), and \(w\). The `VertexAttrib1*` family of commands sets the \(x\) coordinate to the provided single argument while setting \(y\) and \(z\) to 0 and \(w\) to 1. Similarly, `VertexAttrib2*` commands set \(x\) and \(y\) to the specified values, \(z\) to 0 and \(w\) to 1; `VertexAttrib3*` commands set \(x\), \(y\), and \(z\), with \(w\) set to 1, and `VertexAttrib4*` commands set all four coordinates.

The `VertexAttrib*` entry points may also be used to load shader attributes declared as a floating-point matrix. Each column of a matrix takes up one generic 4-component attribute slot out of the `MAX_VERTEX_ATTRIBS` available slots. Matrices are loaded into these slots in column major order. Matrix columns are loaded in increasing slot numbers.

The resulting attribute values are undefined if the base type of the shader attribute at slot *index* is not floating-point (e.g. is signed or unsigned integer). To load current values of a generic shader attribute declared as a signed or unsigned scalar or vector, use the commands

```c
void VertexAttribI{1234}{i ui}(uint index, T values);
void VertexAttribI{1234}{i ui}v(uint index, T values);
void VertexAttribI4{bs ubus}v(uint index, T values);
```

These commands specify values that are extended to full signed or unsigned integers, then loaded into the generic attribute at slot *index* in the same fashion as described above.

The resulting attribute values are undefined if the base type of the shader attribute at slot *index* is floating-point; if the base type is integer and unsigned integer values are supplied (the `VertexAttrib1*ui`, `VertexAttrib1*us`, and `VertexAttrib1*ub` commands); or if the base type is unsigned integer and signed integer values are supplied (the `VertexAttrib1*i`, `VertexAttrib1*s`, and `VertexAttrib1*b` commands).

The error `INVALID_VALUE` is generated by `VertexAttrib*` if *index* is greater than or equal to `MAX_VERTEX_ATTRIBS`.

Setting generic vertex attribute zero specifies a vertex; the four vertex coordinates are taken from the values of attribute zero. A `Vertex2`, `Vertex3`, or `Vertex4` command is completely equivalent to the corresponding `VertexAttrib*` command with an *index* of zero. Setting any other generic vertex attribute updates the current values of the attribute. There are no current values for vertex attribute zero.

There is no aliasing among generic attributes and conventional attributes. In other words, an application can set all `MAX_VERTEX_ATTRIBS` generic attributes and all conventional attributes without fear of one particular attribute overwriting the value of another attribute.
2.8. VERTEX ARRAYS

The state required to support vertex specification consists of four floating-point numbers per texture coordinate set to store the current texture coordinates $s$, $t$, $r$, and $q$, three floating-point numbers to store the three coordinates of the current normal, one floating-point number to store the current fog coordinate, four floating-point values to store the current RGBA color, four floating-point values to store the current RGBA secondary color, one floating-point value to store the current color index, and the value of $\text{MAX_VERTEX_ATTRIBS} - 1$ four-component vectors to store generic vertex attributes.

There is no notion of a current vertex, so no state is devoted to vertex coordinates or generic attribute zero. The initial texture coordinates are $(s, t, r, q) = (0, 0, 0, 1)$ for each texture coordinate set. The initial current normal has coordinates $(0, 0, 1)$. The initial fog coordinate is zero. The initial RGBA color is $(R, G, B, A) = (1, 1, 1, 1)$ and the initial RGBA secondary color is $(0, 0, 0, 1)$. The initial color index is 1. The initial values for all generic vertex attributes are $(0.0, 0.0, 0.0, 1.0)$.

2.8 Vertex Arrays

The vertex specification commands described in section 2.7 accept data in almost any format, but their use requires many command executions to specify even simple geometry. Vertex data may also be placed into arrays that are stored in the client’s address space (described here) or in the server’s address space (described in section 2.9). Blocks of data in these arrays may then be used to specify multiple geometric primitives through the execution of a single GL command. The client may specify up to seven plus the values of $\text{MAX_TEXTURE_COORDS}$ and $\text{MAX_VERTEX_ATTRIBS}$ arrays: one each to store vertex coordinates, normals, colors, secondary colors, color indices, edge flags, fog coordinates, two or more texture coordinate sets, and $\text{MAX_VERTEX_ATTRIBS}$ arrays to store one or more generic vertex attributes. The commands

```c
void VertexPointer(int size, enum type, sizei stride, void *pointer);
void NormalPointer(enum type, sizei stride, void *pointer);
void ColorPointer(int size, enum type, sizei stride, void *pointer);
void SecondaryColorPointer(int size, enum type, sizei stride, void *pointer);
void IndexPointer(enum type, sizei stride, void *pointer);
void EdgeFlagPointer(sizei stride, void *pointer);
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.8. VERTEX ARRAYS

```c
void FogCoordPointer(enum type, sizei stride, void *pointer);
void TexCoordPointer(int size, enum type, sizei stride, void *pointer);
void VertexAttribPointer(uint index, int size, enum type,
    boolean normalized, sizei stride, const void *pointer);
void VertexAttrib1Pointer(uint index, int size, enum type,
    sizei stride, const void *pointer);
```

describe the locations and organizations of these arrays. For each command, `type`
specifies the data type of the values stored in the array. Because edge flags are al-
ways type boolean, `EdgeFlagPointer` has no `type` argument. `size`, when present,
indicates the number of values per vertex that are stored in the array as well as their
component ordering. Because normals are always specified with three values, `Nor-
malPointer` has no `size` argument. Likewise, because color indices and edge flags
are always specified with a single value, `IndexPointer` and `EdgeFlagPointer` also
have no `size` argument. Table 2.5 indicates the allowable values for `size` and `type`
(when present). For `type` the values BYTE, SHORT, INT, FLOAT, HALF_FLOAT, and
DOUBLE indicate types byte, short, int, float, half, and double, respectively; and the values UNSIGNED_BYTE, UNSIGNED_SHORT, and UNSIGNED_INT
indicate types ubyte, ushort, and uint, respectively. The error INVALID_-
VALUE is generated if `size` is specified with a value other than that indicated in the
table, if `size` is BGRA and `type` is not UNSIGNED_BYTE, or by `VertexAttribPointer`
if `size` is BGRA and `normalized` is FALSE.

An INVALID_OPERATION error is generated if any of the *Pointer commands
specifying the location and organization of vertex array data are called while a non-
zero vertex array object is bound (see section 2.10), zero is bound to the ARRAY_-
BUFFER buffer object binding point (see section 2.9.6), and the `pointer` argument
is not NULL.

The `index` parameter in the `VertexAttribPointer` and `VertexAttrib1Pointer`
commands identifies the generic vertex attribute array being described. The er-
ror INVALID_VALUE is generated if `index` is greater than or equal to the value of MAX_VERTEX_ATTRIBS. Generic attribute arrays with integer `type` arguments can
be handled in one of three ways: converted to float by normalizing to [0, 1] or
[−1, 1] as described in equations 2.1 and 2.2, respectively; converted directly to
float, or left as integers. Data for an array specified by `VertexAttribPointer` will
be converted to floating-point by normalizing if `normalized` is TRUE, and converted

---

2 This error makes it impossible to create a vertex array object containing client array pointers,
while still allowing buffer objects to be unbound.
Table 2.5: Vertex array sizes (values per vertex) and data types. The “Integer Handling” column indicates how fixed-point data types are handled: “cast” means that they are converted to floating-point directly, “normalize” means that they are converted to floating-point by normalizing to \([0, 1]\) (for unsigned types) or \([-1, 1]\) (for signed types), “integer” means that they remain as integer values, and “flag” means that either “cast” or “normalized” applies, depending on the setting of the normalized flag in VertexAttribPointer. If size is BGRA, vertex array values are always normalized, irrespective of the “normalize” table entry.
2.8. VERTEX ARRAYS

directly to floating-point otherwise. Data for an array specified by `VertexAttribIPointer` will always be left as integer values; such data are referred to as *pure* integers.

The one, two, three, or four values in an array that correspond to a single vertex comprise an array *element*. When `size` is `BGRA`, it indicates four values. The values within each array element are stored sequentially in memory. However, if `size` is `BGRA`, the first, second, third, and fourth values of each array element are taken from the third, second, first, and fourth values in memory respectively. If `stride` is specified as zero, then array elements are stored sequentially as well. The error `INVALID_VALUE` is generated if `stride` is negative. Otherwise pointers to the `i`th and `(i + 1)`st elements of an array differ by `stride` basic machine units (typically unsigned bytes), the pointer to the `(i + 1)`st element being greater. For each command, `pointer` specifies the location in memory of the first value of the first element of the array being specified.

An individual array is enabled or disabled by calling one of

```c
void EnableClientState(enum array);
void DisableClientState(enum array);
```

with `array` set to `VERTEX_ARRAY`, `NORMAL_ARRAY`, `COLOR_ARRAY`, `SECONDARY_COLOR_ARRAY`, `INDEX_ARRAY`, `EDGE_FLAG_ARRAY`, `FOG_COORD_ARRAY`, or `TEXTURE_COORD_ARRAY`, for the vertex, normal, color, secondary color, color index, edge flag, fog coordinate, or texture coordinate array, respectively.

An individual generic vertex attribute array is enabled or disabled by calling one of

```c
void EnableVertexAttribArray(uint index);
void DisableVertexAttribArray(uint index);
```

where `index` identifies the generic vertex attribute array to enable or disable. The error `INVALID_VALUE` is generated if `index` is greater than or equal to `MAX_VERTEX_ATTRIBS`.

The command

```c
void ClientActiveTexture(enum texture);
```

is used to select the vertex array client state parameters to be modified by the `TexCoordPointer` command and the array affected by `EnableClientState` and `DisableClientState` with parameter `TEXTURE_COORD_ARRAY`. This command sets the client state variable `CLIENT_ACTIVE_TEXTURE`. Each texture coordinate set has

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.8. VERTEX ARRAYS

a client state vector which is selected when this command is invoked. This state
vector includes the vertex array state. This call also selects the texture coordinate
set state used for queries of client state.

Specifying an invalid texture generates the error INVALID_ENUM. Valid values
of texture are the same as for the MultiTexCoord commands described in section 2.7.

The command

void ArrayElement(int i);

transfers the \(i\)th element of every enabled array to the GL. The effect of \(\text{ArrayElement}(i)\) is the same as the effect of the command sequence

\[
\begin{align*}
\text{if (normal array enabled)} & \quad \text{Normal3[type]}v(\text{normal array element } i); \\
\text{if (color array enabled)} & \quad \text{Color[size][type]}v(\text{color array element } i); \\
\text{if (secondary color array enabled)} & \quad \text{SecondaryColor3[type]}v(\text{secondary color array element } i); \\
\text{if (fog coordinate array enabled)} & \quad \text{FogCoord[type]}v(\text{fog coordinate array element } i); \\
\text{for (j = 0; j < textureUnits; j++)} & \quad \text{MultiTexCoord[size][type]}v(\text{TEXTURE0 + } j, \text{texture coordinate set } j \text{ array element } i); \\
\text{if (color index array enabled)} & \quad \text{Index[type]}v(\text{color index array element } i); \\
\text{if (edge flag array enabled)} & \quad \text{EdgeFlagv(\text{edge flag array element } i);}
\end{align*}
\]

for \(j = 1; j < \text{genericAttributes}; j++\) {
\text{if (generic vertex attribute } j \text{ array enabled)} {
\text{if (generic vertex attribute } j \text{ array is a pure integer array)}
\text{VertexAttribI[size][type]}v(\text{\(j\), generic vertex attribute } j \text{ array element } i);
\text{else if (generic vertex attribute } j \text{ array normalization flag is set, and}
\text{type is not FLOAT, HALF_FLOAT, or DOUBLE)}
\text{VertexAttrib[size][N[type]]v(\text{\(j\), generic vertex attribute } j \text{ array element } i);}
\text{else}
\text{VertexAttrib[size][type]}v(\text{\(j\), generic vertex attribute } j \text{ array element } i);
\}
\}

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
if (generic vertex attribute array 0 enabled) {
    if (generic vertex attribute 0 array is a pure integer array)
        VertexAttribI[size][type]v(0, generic vertex attribute 0 array element i);
    else if (generic vertex attribute 0 array normalization flag is set, and
        type is not FLOAT, HALF_FLOAT, or DOUBLE)
        VertexAttribN[size][type]v(0, generic vertex attribute 0 array element i);
    else
        VertexAttr[size][type]v(0, generic vertex attribute 0 array element i);
} else if (vertex array enabled) {
    Vertex[size][type]v(vertex array element i);
}

where textureUnits and genericAttributes give the number of texture coordinate
sets and generic vertex attributes supported by the implementation, respectively.
“[size]” and “[type]” correspond to the size and type of the corresponding array.
For generic vertex attributes, it is assumed that a complete set of vertex attribute
commands exists, even though not all such functions are provided by the GL.

Changes made to array data between the execution of Begin and the corre-
sponding execution of End may affect calls to ArrayElement that are made within
the same Begin/End period in non-sequential ways. That is, a call to ArrayEle-
ment that precedes a change to array data may access the changed data, and a call
that follows a change to array data may access original data.

Specifying \( i < 0 \) results in undefined behavior. Generating the error
INVALID_VALUE is recommended in this case.

Primitive restarting is enabled or disabled by calling one of the commands

    void Enable( enum target );

and

    void Disable( enum target );

with target PRIMITIVE_RESTART. The command

    void PrimitiveRestartIndex( uint index );

specifies the index of a vertex array element that is treated specially when prim-
itive restarting is enabled. This value is called the primitive restart index. When
ArrayElement is called between an execution of Begin and the corresponding ex-
cution of End, if \( i \) is equal to the primitive restart index, then no vertex data is
dereferenced, and no current vertex state is modified. Instead, it is as if End were
2.8. VERTEX ARRAYS

called, followed by a call to Begin where mode is the same as the mode used by the previous Begin.

When one of the *BaseVertex drawing commands specified in section 2.8.1 is used, the primitive restart comparison occurs before the basevertex offset is added to the array index.

2.8.1 Drawing Commands

The command

```c
void DrawArrays( enum mode, int first, sizei count );
```

constructs a sequence of geometric primitives using elements first through first + count − 1 of each enabled array. mode specifies what kind of primitives are constructed, and accepts the same token values as the mode parameter of the Begin command. The effect of

```
DrawArrays( mode, first, count );
```

is the same as the effect of the command sequence

```c
if ( mode or count is invalid )
genenerate appropriate error
else {
    Begin( mode );
    for ( int i = 0; i < count; i++ )
        ArrayElement( first+i );
    End();
}
```

with one exception: the current normal coordinate, color, secondary color, color index, edge flag, fog coordinate, texture coordinates, and generic attribute values are each indeterminate after execution of DrawArrays, if the corresponding array is enabled. Current values corresponding to disabled arrays are not modified by the execution of DrawArrays.

Specifying first < 0 results in undefined behavior. Generating the error INVALID_VALUE is recommended in this case.

The command

```c
void MultiDrawArrays( enum mode, int *first,
    sizei *count, sizei primcount );
```
behaves identically to **DrawArrays** except that `primcount` separate ranges of elements are specified instead. It has the same effect as:

```
for (i = 0; i < primcount; i++) {
  if (count[i] > 0)
    DrawArrays(mode, first[i], count[i]);
}
```

The command

```c
void DrawElements( enum mode, sizei count, enum type,
                  void *indices );
```

constructs a sequence of geometric primitives using the `count` elements whose indices are stored in `indices`. `type` must be one of `UNSIGNED_BYTE`, `UNSIGNED_SHORT`, or `UNSIGNED_INT`, indicating that the index values are of GL type `ubyte`, `ushort`, or `uint` respectively. `mode` specifies what kind of primitives are constructed, and accepts the same token values as the `mode` parameter of the **Begin** command. The effect of

**DrawElements** (`mode`, `count`, `type`, `indices`);

is the same as the effect of the command sequence

```
if ( (mode, count, or type is invalid )
    generate appropriate error
else {
  Begin(mode);
  for (int i = 0; i < count; i++)
    ArrayElement(indices[i]);
  End();
}
```

with one exception: the current normal coordinates, color, secondary color, color index, edge flag, fog coordinate, texture coordinates, and generic attributes are each indeterminate after the execution of **DrawElements**, if the corresponding array is enabled. Current values corresponding to disabled arrays are not modified by the execution of **DrawElements**.

The command

```c
void MultiDrawElements( enum mode, sizei *count,
                        enum type, void **indices, sizei primcount );
```
2.8. VERTEX ARRAYS

behaves identically to DrawElements except that primcount separate lists of elements are specified instead. It has the same effect as:

```c
for (i = 0; i < primcount; i++) {
    if (count[i] > 0)
        DrawElements(mode, count[i], type, indices[i]);
}
```

The command

```c
void DrawRangeElements( enum mode, uint start,
    uint end, sizei count, enum type, void *indices );
```

is a restricted form of DrawElements. mode, count, type, and indices match the corresponding arguments to DrawElements, with the additional constraint that all index values identified by indices must lie between start and end inclusive.

Implementations denote recommended maximum amounts of vertex and index data, which may be queried by calling GetIntegerv with the symbolic constants MAX_ELEMENTS_VERTICES and MAX_ELEMENTS_INDICES. If end − start + 1 is greater than the value of MAX_ELEMENTS_VERTICES, or if count is greater than the value of MAX_ELEMENTS_INDICES, then the call may operate at reduced performance. There is no requirement that all vertices in the range [start, end] be referenced. However, the implementation may partially process unused vertices, reducing performance from what could be achieved with an optimal index set.

The error INVALID_VALUE is generated if end < start. Invalid mode, count, or type parameters generate the same errors as would the corresponding call to DrawElements. It is an error for index values other than the primitive restart index to lie outside the range [start, end], but implementations are not required to check for this. Such indices will cause implementation-dependent behavior.

The internal counter instanceID is a 32-bit integer value which may be read by a vertex shader as gl_InstanceID, as described in section 2.14.4. The value of this counter is always zero, except as noted below.

The command

```c
void DrawArraysInstanced( enum mode, int first,
    sizei count, sizei primcount );
```

behaves identically to DrawArrays except that primcount instances of the range of elements are executed and the value of instanceID advances for each iteration. It has the same effect as:
if (mode or count is invalid) 
generate appropriate error
else {
  for (int i = 0; i < primcount; i++) {
    instanceID = i;
    DrawArrays(mode, first, count);
  }
  instanceID = 0;
}

The command 
void DrawElementsInstanced( enum mode, sizei count,
enum type, const void *indices, sizei primcount );

behaves identically to DrawElements except that primcount instances of the set of 
elements are executed, and the value of instanceID advances for each iteration. It 
has the same effect as:

if (mode, count, or type is invalid) 
generate appropriate error
else {
  for (int i = 0; i < primcount; i++) {
    instanceID = i;
    DrawElements(mode, count, type, indices);
  }
  instanceID = 0;
}

The commands

void DrawElementsBaseVertex( enum mode, sizei count,
enum type, void *indices, int basevertex );
void DrawRangeElementsBaseVertex( enum mode,
uint start, uint end, sizei count, enum type,
void *indices, int basevertex );
void DrawElementsInstancedBaseVertex( enum mode,
sizei count, enum type, const void *indices,
sizei primcount, int basevertex );

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
are equivalent to the commands with the same base name (without the `BaseVertex` suffix), except that the $i$th element transferred by the corresponding draw call will be taken from element $indices[i] + basevertex$ of each enabled array. If the resulting value is larger than the maximum value representable by $type$, it should behave as if the calculation were upconverted to 32-bit unsigned integers (with wrapping on overflow conditions). The operation is undefined if the sum would be negative and should be handled as described in section 2.9.4. For `DrawRangeElementsBaseVertex`, the index values must lie between $start$ and $end$ inclusive, prior to adding the $basevertex$ offset. Index values lying outside the range $[start, end]$ are treated in the same way as `DrawRangeElements`.

The command

```c
void MultiDrawElementsBaseVertex( enum mode, 
    sizei *count, enum type, void **indices, 
    sizei primcount, int *basevertex );
```

behaves identically to `DrawElementsBaseVertex`, except that $primcount$ separate lists of elements are specified instead. It has the same effect as:

```c
for (int i = 0; i < primcount; i++)
    if (count[i] > 0)
        DrawElementsBaseVertex( mode, count[i], type, 
            indices[i], basevertex[i]);
```

The command

```c
void InterleavedArrays( enum format, sizei stride, 
    void *pointer );
```

efficiently initializes the six arrays and their enables to one of 14 configurations. $format$ must be one of 14 symbolic constants: V2F, V3F, C4UB_V2F, C4UB_V3F, C3F_V3F, N3F_V3F, C4F_N3F_V3F, T2F_V3F, T4F_V4F, T2F_C4UB_V3F, T2F_C3F_V3F, T2F_N3F_V3F, T2F_C4F_N3F_V3F, or T4F_C4F_N3F_V4F.

The effect of

```c
InterleavedArrays( format, stride, pointer );
```

is the same as the effect of the command sequence

Table 2.6: Variables that direct the execution of **InterleavedArrays**. $f$ is `sizeof(FLOAT)`. $c$ is 4 times `sizeof(UNSIGNED_BYTE)`, rounded up to the nearest multiple of $f$. All pointer arithmetic is performed in units of `sizeof(UNSIGNED_BYTE)`.
2.8. VERTEX ARRAYS

if (format or stride is invalid)
generate appropriate error
else {
  int str;
  set e_t, e_c, e_n, s_t, s_c, s_v, t_c, p_c, p_n, p_v, and s as a function
  of table 2.6 and the value of format.
  str = stride;
  if (str is zero)
    str = s;
  DisableClientState (EDGE_FLAG_ARRAY);
  DisableClientState (INDEX_ARRAY);
  DisableClientState (SECONDARY_COLOR_ARRAY);
  DisableClientState (FOG_COORD_ARRAY);
  if (e_t) {
    EnableClientState (TEXTURE_COORD_ARRAY);
    TexCoordPointer (s_t, FLOAT, str, pointer);
  } else
    DisableClientState (TEXTURE_COORD_ARRAY);
  if (e_c) {
    EnableClientState (COLOR_ARRAY);
    ColorPointer (s_c, t_c, str, pointer + p_c);
  } else
    DisableClientState (COLOR_ARRAY);
  if (e_n) {
    EnableClientState (NORMAL_ARRAY);
    NormalPointer (FLOAT, str, pointer + p_n);
  } else
    DisableClientState (NORMAL_ARRAY);
  EnableClientState (VERTEX_ARRAY);
  VertexPointer (s_v, FLOAT, str, pointer + p_v);
}

If the number of supported texture units (the value of MAX_TEXTURE_COORDS)
is m and the number of supported generic vertex attributes (the value of MAX_VERTEX_ATTRIBS) is n, then the client state required to implement vertex arrays consists of an integer for the client active texture unit selector, 7 + m + n boolean values, 7 + m + n memory pointers, 7 + m + n integer stride values, 7 + m + n symbolic constants representing array types, 3 + m + n integers representing values per element, n boolean values indicating normalization, n boolean values indicating whether the attribute values are pure integers, and an unsigned integer
representing the restart index.

In the initial state, the client active texture unit selector is TEXTURE0, the boolean values are each false, the memory pointers are each NULL, the strides are each zero, the array types are each FLOAT, the integers representing values per element are each four, the normalized and pure integer flags are each false, and the restart index is zero.

2.9 Buffer Objects

Vertex array data (described in section 2.8) are stored in client memory. It is sometimes desirable to store frequently used client data, such as vertex array and pixel data, in high-performance server memory. GL buffer objects provide a mechanism that clients can use to allocate, initialize, and render from such memory. The name space for buffer objects is the unsigned integers, with zero reserved for the GL.

The command

```c
void GenBuffers(sizei n, uint *buffers);
```

returns \(n\) previously unused buffer object names in \(buffers\). These names are marked as used, for the purposes of \(GenBuffers\) only, but they acquire buffer state only when they are first bound with \(BindBuffer\) (see below), just as if they were unused.

Buffer objects are deleted by calling

```c
void DeleteBuffers(sizei n, const uint *buffers);
```

\(buffers\) contains \(n\) names of buffer objects to be deleted. After a buffer object is deleted it has no contents, and its name is again unused. Unused names in \(buffers\) are silently ignored, as is the value zero.

2.9.1 Creating and Binding Buffer Objects

A buffer object is created by binding an unused name to a buffer target. The binding is effected by calling

```c
void BindBuffer(enum target, uint buffer);
```

\(target\) must be one of the targets listed in table 2.7. If the buffer object named \(buffer\) has not been previously bound, or has been deleted since the last binding, the GL creates a new state vector, initialized with a zero-sized memory buffer and comprising the state values listed in table 2.8.
Buffer objects created by binding an unused name to any of the valid targets are formally equivalent, but the GL may make different choices about storage location and layout based on the initial binding.

**BindBuffer** may also be used to bind an existing buffer object. If the bind is successful no change is made to the state of the newly bound buffer object, and any previous binding to target is broken.

While a buffer object is bound, GL operations on the target to which it is bound affect the bound buffer object, and queries of the target to which a buffer object is bound return state from the bound object. Operations on the target also affect any other bindings of that object.

If a buffer object is deleted while it is bound, all bindings to that object in the current context (i.e. in the thread that called **DeleteBuffers**) are reset to zero. Bindings to that buffer in other contexts and other threads are not affected, but attempting to use a deleted buffer in another thread produces undefined results, including but not limited to possible GL errors and rendering corruption. Using a deleted buffer in another context or thread may not, however, result in program termination.

Initially, each buffer object target is bound to zero. There is no buffer object corresponding to the name zero, so client attempts to modify or query buffer object state for a target bound to zero generate an **INVALID_OPERATION** error.

### Binding Buffer Objects to Indexed Targets

Buffer objects may be bound to *indexed* targets by calling one of the commands
### 2.9. BUFFER OBJECTS

<table>
<thead>
<tr>

</table>

Table 2.8: Buffer object parameters and their values.

```c
void BindBufferRange( enum target, uint index,
                     uint buffer, intptr offset, sizeiptr size );
void BindBufferBase( enum target, uint index, uint buffer );
```

target must be TRANSFORM_FEEDBACK_BUFFER or UNIFORM_BUFFER. Additional language specific to each target is included in sections referred to for each target in table 2.7.

Each target represents an indexed array of buffer object binding points, as well as a single general binding point that can be used by other buffer object manipulation functions (e.g. BindBuffer, MapBuffer). Both commands bind the buffer object named by buffer to both the general binding point, and to the binding point in the array given by index. The error INVALID_VALUE is generated if index is greater than or equal to the number of target-specific indexed binding points.

For BindBufferRange, offset specifies a starting offset into the buffer object buffer, and size specifies the amount of data that can be read from the buffer object while used as an indexed target. Both offset and size are in basic machine units. The error INVALID_VALUE is generated if size is less than or equal to zero or if offset + size is greater than the value of BUFFER_SIZE. Additional errors may be generated if offset violates target-specific alignment requirements.

BindBufferBase is equivalent to calling BindBufferRange with offset zero and size equal to the size of buffer.
2.9. BUFFER OBJECTS

2.9.2 Creating Buffer Object Data Stores

The data store of a buffer object is created and initialized by calling

```c
void BufferData( enum target, sizeiptr size, const void *data, enum usage );
```

with `target` set to one of the targets listed in table 2.7, `size` set to the size of the data store in basic machine units, and `data` pointing to the source data in client memory. If `data` is non-null, then the source data is copied to the buffer object’s data store. If `data` is null, then the contents of the buffer object’s data store are undefined.

`usage` is specified as one of nine enumerated values, indicating the expected application usage pattern of the data store. The values are:

- **STREAM_DRAW** The data store contents will be specified once by the application, and used at most a few times as the source for GL drawing and image specification commands.
- **STREAM_READ** The data store contents will be specified once by reading data from the GL, and queried at most a few times by the application.
- **STREAM_COPY** The data store contents will be specified once by reading data from the GL, and used at most a few times as the source for GL drawing and image specification commands.
- **STATIC_DRAW** The data store contents will be specified once by the application, and used many times as the source for GL drawing and image specification commands.
- **STATIC_READ** The data store contents will be specified once by reading data from the GL, and queried many times by the application.
- **STATIC_COPY** The data store contents will be specified once by reading data from the GL, and used many times as the source for GL drawing and image specification commands.
- **DYNAMIC_DRAW** The data store contents will be respecified repeatedly by the application, and used many times as the source for GL drawing and image specification commands.
- **DYNAMIC_READ** The data store contents will be respecified repeatedly by reading data from the GL, and queried many times by the application.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.9. BUFFER OBJECTS

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUFFER_SIZE</td>
<td>size</td>
</tr>
<tr>
<td>BUFFER_USAGE</td>
<td>usage</td>
</tr>
<tr>

<td>FALSE</td>
</tr>
<tr>
<td>BUFFER_MAP_POINTER</td>
<td>NULL</td>
</tr>
<tr>
<td>BUFFER_MAP_OFFSET</td>
<td>0</td>
</tr>
<tr>
<td>BUFFER_MAP_LENGTH</td>
<td>0</td>
</tr>
</tbody>
</table>

Table 2.9: Buffer object initial state.

**DYNAMIC_COPY** The data store contents will be respecified repeatedly by reading data from the GL, and used many times as the source for GL drawing and image specification commands.

*usage* is provided as a performance hint only. The specified usage value does not constrain the actual usage pattern of the data store.

**BufferData** deletes any existing data store, and sets the values of the buffer object’s state variables as shown in table 2.9.

Clients must align data elements consistent with the requirements of the client platform, with an additional base-level requirement that an offset within a buffer to a datum comprising \( N \) basic machine units be a multiple of \( N \).

If the GL is unable to create a data store of the requested size, the error `OUT_OF_MEMORY` is generated.

To modify some or all of the data contained in a buffer object’s data store, the client may use the command

```c
void BufferSubData( enum target, intptr offset, sizeiptr size, const void *data );
```

with *target* set to one of the targets listed in table 2.7. *offset* and *size* indicate the range of data in the buffer object that is to be replaced, in terms of basic machine units. *data* specifies a region of client memory *size* basic machine units in length, containing the data that replace the specified buffer range. An `INVALID_VALUE` error is generated if *offset* or *size* is less than zero or if *offset* + *size* is greater than the value of `BUFFER_SIZE`. An `INVALID_OPERATION` error is generated if any part of the specified buffer range is mapped with `MapBufferRange` or `MapBuffer` (see section 2.9.3).
2.9. BUFFER OBJECTS

2.9.3 Mapping and Unmapping Buffer Data

All or part of the data store of a buffer object may be mapped into the client’s address space by calling

```c
void *MapBufferRange( enum target, intptr offset,
                      sizeiptr length, bitfield access );
```

with `target` set to one of the targets listed in table 2.7. `offset` and `length` indicate the range of data in the buffer object that is to be mapped, in terms of basic machine units. `access` is a bitfield containing flags which describe the requested mapping. These flags are described below.

If no error occurs, a pointer to the beginning of the mapped range is returned once all pending operations on that buffer have completed, and may be used to modify and/or query the corresponding range of the buffer, according to the following flag bits set in `access`:

- **MAP_READ_BIT** indicates that the returned pointer may be used to read buffer object data. No GL error is generated if the pointer is used to query a mapping which excludes this flag, but the result is undefined and system errors (possibly including program termination) may occur.

- **MAP_WRITE_BIT** indicates that the returned pointer may be used to modify buffer object data. No GL error is generated if the pointer is used to modify a mapping which excludes this flag, but the result is undefined and system errors (possibly including program termination) may occur.

Pointer values returned by `MapBufferRange` may not be passed as parameter values to GL commands. For example, they may not be used to specify array pointers, or to specify or query pixel or texture image data; such actions produce undefined results, although implementations may not check for such behavior for performance reasons.

Mappings to the data stores of buffer objects may have nonstandard performance characteristics. For example, such mappings may be marked as uncachable regions of memory, and in such cases reading from them may be very slow. To ensure optimal performance, the client should use the mapping in a fashion consistent with the values of `BUFFER_USAGE` and `access`. Using a mapping in a fashion inconsistent with these values is liable to be multiple orders of magnitude slower than using normal memory.

The following optional flag bits in `access` may be used to modify the mapping:

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
MAP_INVALIDATE_RANGE_BIT indicates that the previous contents of the specified range may be discarded. Data within this range are undefined with the exception of subsequently written data. No GL error is generated if subsequent GL operations access unwritten data, but the result is undefined and system errors (possibly including program termination) may occur. This flag may not be used in combination with MAP_READ_BIT.

MAP_INVALIDATE_BUFFER_BIT indicates that the previous contents of the entire buffer may be discarded. Data within the entire buffer are undefined with the exception of subsequently written data. No GL error is generated if subsequent GL operations access unwritten data, but the result is undefined and system errors (possibly including program termination) may occur. This flag may not be used in combination with MAP_READ_BIT.

MAP_FLUSH_EXPLICIT_BIT indicates that one or more discrete subranges of the mapping may be modified. When this flag is set, modifications to each subrange must be explicitly flushed by calling FlushMappedBufferRange. No GL error is set if a subrange of the mapping is modified and not flushed, but data within the corresponding subrange of the buffer are undefined. This flag may only be used in conjunction with MAP_WRITE_BIT. When this option is selected, flushing is strictly limited to regions that are explicitly indicated with calls to FlushMappedBufferRange prior to unmap; if this option is not selected UnmapBuffer will automatically flush the entire mapped range when called.

MAP_UNSYNCHRONIZED_BIT indicates that the GL should not attempt to synchronize pending operations on the buffer prior to returning from MapBufferRange. No GL error is generated if pending operations which source or modify the buffer overlap the mapped region, but the result of such previous and any subsequent operations is undefined.

A successful MapBufferRange sets buffer object state values as shown in table 2.10.

Errors
If an error occurs, MapBufferRange returns a NULL pointer.

An INVALID_VALUE error is generated if offset or length is negative, if offset + length is greater than the value of BUFFER_SIZE, or if access has any bits set other than those defined above.

An INVALID_OPERATION error is generated for any of the following conditions:
2.9. BUFFER OBJECTS

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUFFER_ACCESS</td>
<td>Depends on <code>access</code>¹</td>
</tr>
<tr>
<td>BUFFER_ACCESS_FLAGS</td>
<td><code>access</code></td>
</tr>
<tr>
<td>BUFFER_MAPPED</td>
<td>TRUE</td>
</tr>
<tr>
<td>BUFFER_MAP_POINTER</td>
<td>pointer to the data store</td>
</tr>
<tr>
<td>BUFFER_MAP_OFFSET</td>
<td><code>offset</code></td>
</tr>
<tr>
<td>BUFFER_MAP_LENGTH</td>
<td><code>length</code></td>
</tr>
</tbody>
</table>

Table 2.10: Buffer object state set by `MapBufferRange`.

¹ `BUFFER_ACCESS` is set to `READ_ONLY`, `WRITE_ONLY`, or `READ_WRITE` if `access` 
& `(MAP_READ_BIT|MAP_WRITE_BIT)` is respectively `MAP_READ_BIT`, `MAP_WRITE_BIT`, or `MAP_READ_BIT|MAP_WRITE_BIT`.

- The buffer is already in a mapped state.
- Neither `MAP_READ_BIT` nor `MAP_WRITE_BIT` is set.
- `MAP_READ_BIT` is set and any of `MAP_INVALIDATE_RANGE_BIT`, `MAP_INVALIDATE_BUFFER_BIT`, or `MAP_UNSYNCHRONIZED_BIT` is set.
- `MAP_FLUSH_EXPLICIT_BIT` is set and `MAP_WRITE_BIT` is not set.

An `OUT_OF_MEMORY` error is generated if `MapBufferRange` fails because memory for the mapping could not be obtained.

No error is generated if memory outside the mapped range is modified or queried, but the result is undefined and system errors (possibly including program termination) may occur.

The entire data store of a buffer object can be mapped into the client’s address space by calling

```c
void *MapBuffer( enum target, enum access );
```

`MapBuffer` is equivalent to calling `MapBufferRange` with the same `target`, `offset` of zero, `length` equal to the value of `BUFFER_SIZE`, and the `access` bitfield value passed to `MapBufferRange` equal to

- `MAP_READ_BIT`, if `mbaccess` is `READ_ONLY`  
- `MAP_WRITE_BIT`, if `mbaccess` is `WRITE_ONLY`  
- `MAP_READ_BIT|MAP_WRITE_BIT`, if `mbaccess` is `READ_WRITE`

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
and \texttt{mbaccess} is the value of the \texttt{access} \texttt{enum} parameter passed to \texttt{MapBuffer}.

\texttt{INVALID_ENUM} is generated if \texttt{access} is not one of the values described above.

Other errors are generated as described above for \texttt{MapBufferRange}.

If a buffer is mapped with the \texttt{MAP_FLUSH_EXPLICIT_BIT} flag, modifications to the mapped range may be indicated by calling

```
void FlushMappedBufferRange( enum target, intptr offset, sizeiptr length );
```

with \texttt{target} set to one of the targets listed in table 2.7. \texttt{offset} and \texttt{length} indicate a modified subrange of the mapping, in basic machine units. The specified subrange to flush is relative to the start of the currently mapped range of buffer. \texttt{FlushMappedBufferRange} may be called multiple times to indicate distinct subranges of the mapping which require flushing.

**Errors**

An \texttt{INVALID_VALUE} error is generated if \texttt{offset} or \texttt{length} is negative, or if \texttt{offset} + \texttt{length} exceeds the size of the mapping.

An \texttt{INVALID_OPERATION} error is generated if zero is bound to \texttt{target}.

An \texttt{INVALID_OPERATION} error is generated if the buffer bound to \texttt{target} is not mapped, or is mapped without the \texttt{MAP_FLUSH_EXPLICIT_BIT} flag.

**Unmapping Buffers**

After the client has specified the contents of a mapped buffer range, and before the data in that range are dereferenced by any GL commands, the mapping must be relinquished by calling

```
boolean UnmapBuffer( enum target );
```

with \texttt{target} set to one of the targets listed in table 2.7. Unmapping a mapped buffer object invalidates the pointer to its data store and sets the object’s \texttt{BUFFER\_MAPPED}, \texttt{BUFFER\_MAP\_POINTER}, \texttt{BUFFER\_ACCESS\_FLAGS}, \texttt{BUFFER\_MAP\_OFFSET}, and \texttt{BUFFER\_MAP\_LENGTH} state variables to the initial values shown in table 2.9.

\texttt{UnmapBuffer} returns \texttt{TRUE} unless data values in the buffer’s data store have become corrupted during the period that the buffer was mapped. Such corruption can be the result of a screen resolution change or other window system-dependent event that causes system heaps such as those for high-performance graphics memory to be discarded. GL implementations must guarantee that such corruption can
occur only during the periods that a buffer’s data store is mapped. If such corruption has occurred, \texttt{UnmapBuffer} returns \texttt{FALSE}, and the contents of the buffer’s data store become undefined.

If the buffer data store is already in the unmapped state, \texttt{UnmapBuffer} returns \texttt{FALSE}, and an \texttt{INVALID_OPERATION} error is generated. However, unmapping that occurs as a side effect of buffer deletion or reinitialization is not an error.

**Effects of Mapping Buffers on Other GL Commands**

Most, but not all GL commands will detect attempts to read data from a mapped buffer object. When such an attempt is detected, an \texttt{INVALID_OPERATION} error will be generated. Any command which does not detect these attempts, and performs such an invalid read, has undefined results and may result in GL interruption or termination.

**2.9.4 Effects of Accessing Outside Buffer Bounds**

Most, but not all GL commands operating on buffer objects will detect attempts to read from or write to a location in a bound buffer object at an offset less than zero, or greater than or equal to the buffer’s size. When such an attempt is detected, a GL error will be generated. Any command which does not detect these attempts, and performs such an invalid read or write, has undefined results, and may result in GL interruption or termination.

**2.9.5 Copying Between Buffers**

All or part of the data store of a buffer object may be copied to the data store of another buffer object by calling

\begin{verbatim}
void *CopyBufferSubData( enum readtarget,
    enum writetarget, intptr readoffset, intptr writeoffset,
    sizeiptr size);
\end{verbatim}

with \texttt{readtarget} and \texttt{writetarget} each set to one of the targets listed in table 2.7. While any of these targets may be used, the \texttt{COPY_READ_BUFFER} and \texttt{COPY_WRITE_BUFFER} targets are provided specifically for copies, so that they can be done without affecting other buffer binding targets that may be in use. \texttt{writeoffset} and \texttt{size} specify the range of data in the buffer object bound to \texttt{writetarget} that is to be replaced, in terms of basic machine units. \texttt{readoffset} and \texttt{size} specify the range of data in the buffer object bound to \texttt{readtarget} that is to be copied to the corresponding region of \texttt{writetarget}.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.9. BUFFER OBJECTS

An **INVALID_VALUE** error is generated if any of `readoffset`, `writeoffset`, or `size` are negative, if `readoffset + size` exceeds the size of the buffer object bound to `readtarget`, or if `writeoffset + size` exceeds the size of the buffer object bound to `writetarget`.

An **INVALID_VALUE** error is generated if the same buffer object is bound to both `readtarget` and `writetarget`, and the ranges `[readoffset, readoffset + size)` and `[writeoffset, writeoffset + size)` overlap.

An **INVALID_OPERATION** error is generated if zero is bound to `readtarget` or `writetarget`.

An **INVALID_OPERATION** error is generated if the buffer objects bound to either `readtarget` or `writetarget` are mapped.

2.9.6 Vertex Arrays in Buffer Objects

Blocks of vertex array data may be stored in buffer objects with the same format and layout options supported for client-side vertex arrays. However, it is expected that GL implementations will (at minimum) be optimized for data with all components represented as floats, as well as for color data with components represented as either floats or unsigned bytes. A buffer object binding point is added to the client state associated with each vertex array type. The commands that specify the locations and organizations of vertex arrays copy the buffer object name that is bound to `ARRAY_BUFFER` to the binding point corresponding to the vertex array of the type being specified. For example, the `VertexAttribPointer` command copies the value of `ARRAY_BUFFER_BINDING` (the queriable name of the buffer binding corresponding to the target `ARRAY_BUFFER`) to the client state variable `VERTEX_ATTRIB_ARRAY_BUFFER_BINDING` for the specified `index`.

Rendering commands `ArrayElement`, `DrawArrays`, and the other drawing commands defined in section 2.8.1 operate as previously defined, except that data for enabled vertex and attrib arrays are sourced from buffers if the array’s buffer binding is non-zero. When an array is sourced from a buffer object, the pointer value of that array is used to compute an offset, in basic machine units, into the data store of the buffer object. This offset is computed by subtracting a null pointer from the pointer value, where both pointers are treated as pointers to basic machine units.

It is acceptable for vertex or attrib arrays to be sourced from any combination of client memory and various buffer objects during a single rendering operation.
2.9. BUFFER OBJECTS

2.9.7 Array Indices in Buffer Objects

Blocks of array indices may be stored in buffer objects with the same format options that are supported for client-side index arrays. Initially zero is bound to `ELEMENT_ARRAY_BUFFER`, indicating that `DrawElements` and `DrawRangeElements` are to source their indices from arrays passed as their `indices` parameters, and that `MultiDrawElements` is to source its indices from the array of pointers to arrays passed in as its `indices` parameter.

A buffer object is bound to `ELEMENT_ARRAY_BUFFER` by calling `BindBuffer` with `target` set to `ELEMENT_ARRAY_BUFFER`, and `buffer` set to the name of the buffer object. If no corresponding buffer object exists, one is initialized as defined in section 2.9.

While a non-zero buffer object name is bound to `ELEMENT_ARRAY_BUFFER`, `DrawElements`, `DrawRangeElements`, and `DrawElementsInstanced` source their indices from that buffer object, using their `indices` parameters as offsets into the buffer object in the same fashion as described in section 2.9.6. `DrawElementsBaseVertex`, `DrawRangeElementsBaseVertex`, and `DrawElementsInstancedBaseVertex` also source their indices from that buffer object, adding the `basevertex` offset to the appropriate vertex index as a final step before indexing into the vertex buffer; this does not affect the calculation of the base pointer for the index array. Finally, `MultiDrawElements` and `MultiDrawElementsBaseVertex` also source their indices from that buffer object, using its `indices` parameter as a pointer to an array of pointers that represent offsets into the buffer object.

In some cases performance will be optimized by storing indices and array data in separate buffer objects, and by creating those buffer objects with the corresponding binding points.

2.9.8 Buffer Object State

The state required to support buffer objects consists of binding names for the array buffer, element buffer, pixel unpack buffer, and pixel pack buffer. Additionally, each vertex array has an associated binding so there is a buffer object binding for each of the vertex array, normal array, color array, index array, multiple texture coordinate arrays, edge flag array, secondary color array, fog coordinate array, and vertex attribute arrays. The initial values for all buffer object bindings is zero.

The state of each buffer object consists of a buffer size in basic machine units, a usage parameter, an access parameter, a mapped boolean, two integers for the offset and size of the mapped region, a pointer to the mapped buffer (`NULL` if unmapped), and the sized array of basic machine units for the buffer data.
2.10 Vertex Array Objects

The buffer objects that are to be used by the vertex stage of the GL are collected together to form a vertex array object. All state related to the definition of data used by the vertex processor is encapsulated in a vertex array object.

The command

```c
void GenVertexArrays( sizei n, uint *arrays );
```

returns \( n \) previous unused vertex array object names in `arrays`. These names are marked as used, for the purposes of `GenVertexArrays` only, but they acquire array state only when they are first bound.

Vertex array objects are deleted by calling

```c
void DeleteVertexArrays( sizei n, const uint *arrays );
```

`arrays` contains \( n \) names of vertex array objects to be deleted. Once a vertex array object is deleted it has no contents and its name is again unused. If a vertex array object that is currently bound is deleted, the binding for that object reverts to zero and the default vertex array becomes current. Unused names in `arrays` are silently ignored, as is the value zero.

A vertex array object is created by binding a name returned by `GenVertexArrays` with the command

```c
void BindVertexArray( uint array );
```

`array` is the vertex array object name. The resulting vertex array object is a new state vector, comprising all the state values listed in tables 6.7-6.10.

`BindVertexArray` may also be used to bind an existing vertex array object. If the bind is successful no change is made to the state of the bound vertex array object, and any previous binding is broken.

The currently bound vertex array object is used for all commands which modify vertex array state, such as `VertexAttribPointer` and `EnableVertexAttribArray`; all commands which draw from vertex arrays, such as `DrawArrays` and `DrawElements`; and all queries of vertex array state (see chapter 6).

`BindVertexArray` fails and an `INVALID_OPERATION` error is generated if `array` is not zero or a name returned from a previous call to `GenVertexArrays`, or if such a name has since been deleted with `DeleteVertexArrays`.
2.11 Rectangles

There is a set of GL commands to support efficient specification of rectangles as two corner vertices.

```c
void Rect(sfd)( T x1, T y1, T x2, T y2 );
void Rect[sfd]v(T v1[2], T v2[2]);
```

Each command takes either four arguments organized as two consecutive pairs of \((x,y)\) coordinates, or two pointers to arrays each of which contains an \(x\) value followed by a \(y\) value. The effect of the `Rect` command

```c
Rect (x1, y1, x2, y2);
```

is exactly the same as the following sequence of commands:

```c
Begin (POLYGON);
Vertex2 (x1, y1);
Vertex2 (x2, y1);
Vertex2 (x2, y2);
Vertex2 (x1, y2);
End();
```

The appropriate `Vertex2` command would be invoked depending on which of the `Rect` commands is issued.

2.12 Fixed-Function Vertex Transformations

This section and the following discussion through section 2.13 describe the state values and operations necessary for transforming vertex attributes according to a fixed-functionality method. An alternate programmable method for transforming vertex attributes is described in section 2.14.

Vertices, normals, and texture coordinates are transformed before their coordinates are used to produce an image in the framebuffer. We begin with a description of how vertex coordinates are transformed and how this transformation is controlled.

Figure 2.9 diagrams the sequence of transformations that are applied to vertices. The vertex coordinates that are presented to the GL are termed `object coordinates`. The `model-view` matrix is applied to these coordinates to yield `eye coordinates`. Then another matrix, called the `projection` matrix, is applied to eye coordinates to yield `clip coordinates`. Clip coordinates are further processed as described in section 2.16.
Object coordinates, eye coordinates, and clip coordinates are four-dimensional, consisting of $x, y, z,$ and $w$ coordinates (in that order). The model-view and projection matrices are thus $4 \times 4$.

If a vertex in object coordinates is given by \( \begin{pmatrix} x_O \\ y_O \\ z_O \\ w_O \end{pmatrix} \) and the model-view matrix is $M$, then the vertex’s eye coordinates are found as

\[
\begin{pmatrix} x_E \\ y_E \\ z_E \\ w_E \end{pmatrix} = M \begin{pmatrix} x_O \\ y_O \\ z_O \\ w_O \end{pmatrix}.
\]

Similarly, if $P$ is the projection matrix, then the vertex’s clip coordinates are

\[
\begin{pmatrix} x_C \\ y_C \\ z_C \\ w_C \end{pmatrix} = P \begin{pmatrix} x_E \\ y_E \\ z_E \\ w_E \end{pmatrix}.
\]

2.12.1 Matrices

The projection matrix and model-view matrix are set and modified with a variety of commands. The affected matrix is determined by the current matrix mode.
2.12. FIXED-FUNCTION VERTEX TRANSFORMATIONS

Current matrix mode is set with

```c
voidMatrixMode( enum mode );
```

which takes one of the pre-defined constants TEXTURE, MODELVIEW, COLOR, or PROJECTION as the argument value. TEXTURE is described later in section 2.12.1, and COLOR is described in section 3.7.3. If the current matrix mode is MODELVIEW, then matrix operations apply to the model-view matrix; if PROJECTION, then they apply to the projection matrix.

The two basic commands for affecting the current matrix are

```c
void LoadMatrix{fd}( T m[16] );
void MultMatrix{fd}( T m[16] );
```

**LoadMatrix** takes a pointer to a $4 \times 4$ matrix stored in column-major order as 16 consecutive floating-point values, i.e. as

\[
\begin{pmatrix}
a_1 & a_5 & a_9 & a_{13} \\
a_2 & a_6 & a_{10} & a_{14} \\
a_3 & a_7 & a_{11} & a_{15} \\
a_4 & a_8 & a_{12} & a_{16}
\end{pmatrix}.
\]

(This differs from the standard row-major C ordering for matrix elements. If the standard ordering is used, all of the subsequent transformation equations are transposed, and the columns representing vectors become rows.)

The specified matrix replaces the current matrix with the one pointed to. **MultMatrix** takes the same type argument as **LoadMatrix**, but multiplies the current matrix by the one pointed to and replaces the current matrix with the product. If $C$ is the current matrix and $M$ is the matrix pointed to by **MultMatrix**’s argument, then the resulting current matrix, $C'$, is

$$C' = C \cdot M.$$  

The commands

```c
void LoadTransposeMatrix{fd}( T m[16] );
void MultTransposeMatrix{fd}( T m[16] );
```

take pointers to $4 \times 4$ matrices stored in row-major order as 16 consecutive floating-point values, i.e. as
The effect of
\texttt{LoadTransposeMatrix(fd) (m);}

is the same as the effect of
\texttt{LoadMatrix(fd) (m^T);}

The effect of
\texttt{MultTransposeMatrix(fd) (m);}

is the same as the effect of
\texttt{MultMatrix(fd) (m^T);}

The command
\texttt{void LoadIdentity(void);} 

effectively calls \texttt{LoadMatrix} with the identity matrix:

\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{pmatrix}
\]

There are a variety of other commands that manipulate matrices. \texttt{Rotate}, \texttt{Translate}, \texttt{Scale}, \texttt{Frustum}, and \texttt{Ortho} manipulate the current matrix. Each computes a matrix and then invokes \texttt{MultMatrix} with this matrix. In the case of

\texttt{void Rotate(fd)( T \theta, T x, T y, T z);} 

\(\theta\) gives an angle of rotation in degrees; the coordinates of a vector \(v\) are given by \(v = (x \ y \ z)^T\). The computed matrix is a counter-clockwise rotation about the line through the origin with the specified axis when that axis is pointing up (i.e. the right-hand rule determines the sense of the rotation angle). The matrix is thus
2.12. FIXED-FUNCTION VERTEX TRANSFORMATIONS

\[
\begin{pmatrix}
0 & R & 0 \\
0 & 0 & 0 \\
0 & 0 & 1
\end{pmatrix}.
\]

Let \( u = v / ||v|| = (x', y', z')^T \). If

\[
S = \begin{pmatrix}
0 & -z' & y' \\
z' & 0 & -x' \\
-y' & x' & 0
\end{pmatrix}
\]

then

\[
R = uu^T + \cos \theta (I - uu^T) + \sin \theta S.
\]

The arguments to

\[
\text{void Translate}\{\text{fd}\}(T_x, T_y, T_z);
\]

give the coordinates of a translation vector as \((x \ y \ z)^T\). The resulting matrix is a translation by the specified vector:

\[
\begin{pmatrix}
1 & 0 & 0 & x \\
0 & 1 & 0 & y \\
0 & 0 & 1 & z \\
0 & 0 & 0 & 1
\end{pmatrix}.
\]

\[
\text{void Scale}\{\text{fd}\}(T_x, T_y, T_z);
\]

produces a general scaling along the \(x\)-, \(y\)-, and \(z\)-axes. The corresponding matrix is

\[
\begin{pmatrix}
x & 0 & 0 & 0 \\
0 & y & 0 & 0 \\
0 & 0 & z & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}.
\]

For

\[
\text{void Frustum}(\text{double } l, \text{ double } r, \text{ double } b, \text{ double } t, \\
\text{ double } n, \text{ double } f);
\]
the coordinates \((l \ b \ - \ n)^T\) and \((r \ t \ - \ n)^T\) specify the points on the near clipping plane that are mapped to the lower left and upper right corners of the window, respectively (assuming that the eye is located at \((0 \ 0 \ 0)^T\)). \(f\) gives the distance from the eye to the far clipping plane. If either \(n\) or \(f\) is less than or equal to zero, \(l\) is equal to \(r\), \(b\) is equal to \(t\), or \(n\) is equal to \(f\), the error \texttt{INVALID\_VALUE} results. The corresponding matrix is
\[
\begin{pmatrix}
\frac{2n}{r-l} & 0 & \frac{r+l}{r-l} & 0 \\
0 & \frac{2n}{t-b} & \frac{t+b}{t-b} & 0 \\
0 & 0 & \frac{f+n}{f-n} & \frac{-2fn}{f-n} \\
0 & 0 & -1 & 0
\end{pmatrix}.
\]

```c
void Ortho(double l, double r, double b, double t, double n, double f);
```

describes a matrix that produces parallel projection. \((l \ b \ - \ n)^T\) and \((r \ t \ - \ n)^T\) specify the points on the near clipping plane that are mapped to the lower left and upper right corners of the window, respectively. \(f\) gives the distance from the eye to the far clipping plane. If \(l\) is equal to \(r\), \(b\) is equal to \(t\), or \(n\) is equal to \(f\), the error \texttt{INVALID\_VALUE} results. The corresponding matrix is
\[
\begin{pmatrix}
\frac{2}{r-l} & 0 & \frac{r+l}{r-l} & 0 \\
0 & \frac{2}{t-b} & \frac{t+b}{t-b} & 0 \\
0 & 0 & \frac{f+n}{f-n} & \frac{-2fn}{f-n} \\
0 & 0 & -1 & 0
\end{pmatrix}.
\]

For each texture coordinate set, a \(4 \times 4\) matrix is applied to the corresponding texture coordinates. This matrix is applied as
\[
\begin{pmatrix}
m_1 & m_5 & m_9 & m_{13} \\
m_2 & m_6 & m_{10} & m_{14} \\
m_3 & m_7 & m_{11} & m_{15} \\
m_4 & m_8 & m_{12} & m_{16}
\end{pmatrix}
\begin{pmatrix}
s \\
t \\
r \\
\end{pmatrix},
\]

where the left matrix is the current texture matrix. The matrix is applied to the coordinates resulting from texture coordinate generation (which may simply be the current texture coordinates), and the resulting transformed coordinates become the texture coordinates associated with a vertex. Setting the matrix mode to \texttt{TEXTURE} causes the already described matrix operations to apply to the texture matrix.

The active texture unit selector (see section 3.9) specifies the texture coordinate set accessed by commands involving texture coordinate processing. Such
commands include those accessing the current matrix stack (if \texttt{MATRIX\_MODE} is \texttt{TEXTURE}), \texttt{TexEnv} commands controlling point sprite coordinate replacement (see section 3.4), \texttt{TexGen} (section 2.12.3), \texttt{Enable/Disable} (if any texture coordinate generation enum is selected), as well as queries of the current texture coordinates and current raster texture coordinates. If the texture coordinate set number corresponding to the current value of \texttt{ACTIVE\_TEXTURE} is greater than or equal to the implementation-dependent constant \texttt{MAX\_TEXTURE\_COORDS}, the error \texttt{INVALID\_OPERATION} is generated by any such command.

There is a stack of matrices for each of matrix modes \texttt{MODELVIEW}, \texttt{PROJECTION}, and \texttt{COLOR}, and for each texture unit. For \texttt{MODELVIEW} mode, the stack depth is at least 32 (that is, there is a stack of at least 32 model-view matrices). For the other modes, the depth is at least 2. Texture matrix stacks for all texture units have the same depth. The current matrix in any mode is the matrix on the top of the stack for that mode.

\begin{verbatim}
void PushMatrix(void);
\end{verbatim}

pushes the stack down by one, duplicating the current matrix in both the top of the stack and the entry below it.

\begin{verbatim}
void PopMatrix(void);
\end{verbatim}

pops the top entry off of the stack, replacing the current matrix with the matrix that was the second entry in the stack. The pushing or popping takes place on the stack corresponding to the current matrix mode. Popping a matrix off a stack with only one entry generates the error \texttt{STACK\_UNDERFLOW}; pushing a matrix onto a full stack generates \texttt{STACK\_OVERFLOW}.

When the current matrix mode is \texttt{TEXTURE}, the texture matrix stack of the active texture unit is pushed or popped.

The state required to implement transformations consists of a four-valued integer indicating the current matrix mode, one stack of at least two $4 \times 4$ matrices for each of \texttt{COLOR}, \texttt{PROJECTION}, and each texture coordinate set, \texttt{TEXTURE}; and a stack of at least 32 $4 \times 4$ matrices for \texttt{MODELVIEW}. Each matrix stack has an associated stack pointer. Initially, there is only one matrix on each stack, and all matrices are set to the identity. The initial matrix mode is \texttt{MODELVIEW}.

### 2.12.2 Normal Transformation

Finally, we consider how the model-view matrix and transformation state affect normals. Before use in lighting, normals are transformed to eye coordinates by a
2.12. FIXED-FUNCTION VERTEX TRANSFORMATIONS

matrix derived from the model-view matrix. Rescaling and normalization operations are performed on the transformed normals to make them unit length prior to use in lighting. Rescaling and normalization are controlled by calling \textbf{Enable} and \textbf{Disable} with \textit{target} equal to \texttt{RESCALE\_NORMAL} or \texttt{NORMALIZE}. This requires two bits of state. The initial state is for normals not to be rescaled or normalized.

If the model-view matrix is \( M \), then the normal is transformed to eye coordinates by:

\[
\begin{pmatrix}
  n_x' \\
  n_y' \\
  n_z'
\end{pmatrix} = \begin{pmatrix}
  n_x \\
  n_y \\
  n_z
\end{pmatrix} \cdot M^{-1}
\]

where, if \( \begin{pmatrix}
  x \\
  y \\
  z \\
  w
\end{pmatrix} \) are the associated vertex coordinates, then

\[
q = \begin{cases}
  0, & w = 0, \\
  -\begin{pmatrix}
  n_x \\
  n_y \\
  n_z
\end{pmatrix} \cdot \begin{pmatrix}
  x \\
  y \\
  z
\end{pmatrix}, & w \neq 0
\end{cases}
\]

(2.7)

Implementations may choose instead to transform \( \begin{pmatrix}
  n_x \\
  n_y \\
  n_z
\end{pmatrix} \) to eye coordinates using

\[
\begin{pmatrix}
  n_x' \\
  n_y' \\
  n_z'
\end{pmatrix} = \begin{pmatrix}
  n_x \\
  n_y \\
  n_z
\end{pmatrix} \cdot M_{u\cdot}^{-1}
\]

where \( M_u \) is the upper leftmost 3x3 matrix taken from \( M \).

Rescale multiplies the transformed normals by a scale factor

\[
\begin{pmatrix}
  n_x'' \\
  n_y'' \\
  n_z''
\end{pmatrix} = f \begin{pmatrix}
  n_x' \\
  n_y' \\
  n_z'
\end{pmatrix}
\]

If rescaling is disabled, then \( f = 1 \). If rescaling is enabled, then \( f \) is computed as (\( m_{ij} \) denotes the matrix element in row \( i \) and column \( j \) of \( M^{-1} \), numbering the topmost row of the matrix as row 1 and the leftmost column as column 1)

\[
f = \frac{1}{\sqrt{m_{31}^2 + m_{32}^2 + m_{33}^2}}
\]

Note that if the normals sent to GL were unit length and the model-view matrix uniformly scales space, then rescale makes the transformed normals unit length.

Alternatively, an implementation may choose \( f \) as

\[
f = \frac{1}{\sqrt{n_{x'}^2 + n_{y'}^2 + n_{z'}^2}}
\]
recomputing $f$ for each normal. This makes all non-zero length normals unit length regardless of their input length and the nature of the model-view matrix.

After rescaling, the final transformed normal used in lighting, $n_f$, is computed as

$$n_f = m \begin{pmatrix} n'_x & n'_y & n'_z \end{pmatrix}$$

If normalization is disabled, then $m = 1$. Otherwise

$$m = \frac{1}{\sqrt{n'_x^2 + n'_y^2 + n'_z^2}}$$

Because we specify neither the floating-point format nor the means for matrix inversion, we cannot specify behavior in the case of a poorly-conditioned (nearly singular) model-view matrix $M$. In case of an exactly singular matrix, the transformed normal is undefined. If the GL implementation determines that the model-view matrix is uninvertible, then the entries in the inverted matrix are arbitrary. In any case, neither normal transformation nor use of the transformed normal may lead to GL interruption or termination.

### 2.12.3 Generating Texture Coordinates

Texture coordinates associated with a vertex may either be taken from the current texture coordinates or generated according to a function dependent on vertex coordinates. The command

```c
void TexGen[ifd]( enum coord, enum pname, T param );
void TexGen[ifd]v( enum coord, enum pname, T params );
```

controls texture coordinate generation. $coord$ must be one of the constants $S$, $T$, $R$, or $Q$, indicating that the pertinent coordinate is the $s$, $t$, $r$, or $q$ coordinate, respectively. In the first form of the command, $param$ is a symbolic constant specifying a single-valued texture generation parameter; in the second form, $params$ is a pointer to an array of values that specify texture generation parameters. $pname$ must be one of the three symbolic constants $TEXTURE_GEN_MODE$, $OBJECT_PLANE$, or $EYE_PLANE$. If $pname$ is $TEXTURE_GEN_MODE$, then either $params$ points to or $param$ is an integer that is one of the symbolic constants $OBJECT_LINEAR$, $EYE_LINEAR$, $SPHERE_MAP$, $REFLECTION_MAP$, or $NORMAL_MAP$.

If $TEXTURE_GEN_MODE$ indicates $OBJECT_LINEAR$, then the generation function for the coordinate indicated by $coord$ is

$$g = p_1x_o + p_2y_o + p_3z_o + p_4w_o.$$
2.12. FIXED-FUNCTION VERTEX TRANSFORMATIONS

\[ x, y, z, \text{ and } w \text{ are the object coordinates of the vertex.} \]

\[ p_1, \ldots, p_4 \text{ are specified by calling TexGen with } pname \text{ set to OBJECT_PLANE in which case } params \text{ points to an array containing } p_1, \ldots, p_4. \]

There is a distinct group of plane equation coefficients for each texture coordinate; coord indicates the coordinate to which the specified coefficients pertain.

If TEXTURE_GEN_MODE indicates EYE_LINEAR, then the function is

\[ g = p'_1 x_e + p'_2 y_e + p'_3 z_e + p'_4 w_e \]

where

\[ (p'_1, p'_2, p'_3, p'_4) = (p_1, p_2, p_3, p_4) M^{-1} \]

\[ x_e, y_e, z_e, \text{ and } w_e \text{ are the eye coordinates of the vertex.} \]

\[ p_1, \ldots, p_4 \text{ are set by calling TexGen with } pname \text{ set to EYE_PLANE in correspondence with setting the coefficients in the OBJECT_PLANE case.} \]

\[ M \text{ is the model-view matrix in effect when } p_1, \ldots, p_4 \text{ are specified. Computed texture coordinates may be inaccurate or undefined if } M \text{ is poorly conditioned or singular.} \]

When used with a suitably constructed texture image, calling TexGen with TEXTURE_GEN_MODE indicating SPHERE_MAP can simulate the reflected image of a spherical environment on a polygon. SPHERE_MAP texture coordinates are generated as follows. Denote the unit vector pointing from the origin to the vertex (in eye coordinates) by \( u \). Denote the current normal, after transformation to eye coordinates, by \( n_f \). Let \( r = (r_x, r_y, r_z)^T \), the reflection vector, be given by

\[ r = u - 2n_f T (n_f u), \]

and let \( m = 2 \sqrt{r_x^2 + r_y^2 + (r_z + 1)^2} \). Then the value assigned to an s coordinate (the first TexGen argument value is \( s \)) is \( s = r_x/m + \frac{1}{2} \); the value assigned to a t coordinate is \( t = r_y/m + \frac{1}{2} \). Calling TexGen with a coord of either \( R \) or \( Q \) when \( pname \) indicates SPHERE_MAP generates the error INVALID_ENUM.

If TEXTURE_GEN_MODE indicates REFLECTION_MAP, compute the reflection vector \( r \) as described for the SPHERE_MAP mode. Then the value assigned to an s coordinate is \( s = r_x \); the value assigned to a t coordinate is \( t = r_y \); and the value assigned to an r coordinate is \( r = r_z \). Calling TexGen with a coord of \( Q \) when \( pname \) indicates REFLECTION_MAP generates the error INVALID_ENUM.

If TEXTURE_GEN_MODE indicates NORMAL_MAP, compute the normal vector \( n_f \) as described in section 2.12.2. Then the value assigned to an s coordinate is \( s = n_{fx} \); the value assigned to a t coordinate is \( t = n_{fy} \); and the value assigned to an r coordinate is \( r = n_{fz} \) (the values \( n_{fx}, n_{fy}, \text{ and } n_{fz} \) are the components of \( n_f \).) Calling TexGen with a coord of \( Q \) when \( pname \) indicates NORMAL_MAP generates the error INVALID_ENUM.
A texture coordinate generation function is enabled or disabled using **Enable** and **Disable** with an argument of **TEXTURE_GEN_S**, **TEXTURE_GEN_T**, **TEXTURE_GEN_R**, or **TEXTURE_GEN_Q** (each indicates the corresponding texture coordinate). When enabled, the specified texture coordinate is computed according to the current **EYE_LINEAR**, **OBJECT_LINEAR** or **SPHERE_MAP** specification, depending on the current setting of **TEXTURE_GEN_MODE** for that coordinate. When disabled, subsequent vertices will take the indicated texture coordinate from the current texture coordinates.

The state required for texture coordinate generation for each texture unit comprises a five-valued integer for each coordinate indicating coordinate generation mode, and a bit for each coordinate to indicate whether texture coordinate generation is enabled or disabled. In addition, four coefficients are required for the four coordinates for each of **EYE_LINEAR** and **OBJECT_LINEAR**. The initial state has the texture generation function disabled for all texture coordinates. The initial values of \( p_i \) for \( s \) are all 0 except \( p_1 \) which is one; for \( t \) all the \( p_i \) are zero except \( p_2 \), which is 1. The values of \( p_i \) for \( r \) and \( q \) are all 0. These values of \( p_i \) apply for both the **EYE_LINEAR** and **OBJECT_LINEAR** versions. Initially all texture generation modes are **EYE_LINEAR**.

### 2.13 Fixed-Function Vertex Lighting and Coloring

Figures 2.10 and 2.11 diagram the processing of RGBA colors and color indices before rasterization. Incoming colors arrive in one of several formats. R, G, B, and A components specified with unsigned and signed integer versions of the **Color** command are converted to floating-point as described in equations 2.1 and 2.2, respectively. As a result of limited precision, some converted values will not be represented exactly. In color index mode, a single-valued color index is not mapped.

Next, lighting, if enabled, produces either a color index or primary and secondary colors. If lighting is disabled, the current color index or current color (primary color) and current secondary color are used in further processing. After lighting, RGBA colors may be clamped to the range \([0, 1]\) as described in section 2.13.6. A color index is converted to fixed-point and then its integer portion is masked (see section 2.13.6). After clamping or masking, a primitive may be **flatshaded**, indicating that all vertices of the primitive are to have the same colors. Finally, if a primitive is clipped, then colors (and texture coordinates) must be computed at the vertices introduced or modified by clipping.
2.13. FIXED-FUNCTION VERTEX LIGHTING AND COLORING

Figure 2.10. Processing of RGBA colors. The heavy dotted lines indicate both primary and secondary vertex colors, which are processed in the same fashion. $k$ is the minimum required bit width of the integer type representing a color component.

Figure 2.11. Processing of color indices. $n$ is the number of bits in a color index.
2.13. FIXED-FUNCTION VERTEX LIGHTING AND COLORING

2.13.1 Lighting

GL lighting computes colors for each vertex sent to the GL. This is accomplished by applying an equation defined by a client-specified lighting model to a collection of parameters that can include the vertex coordinates, the coordinates of one or more light sources, the current normal, and parameters defining the characteristics of the light sources and a current material. The following discussion assumes that the GL is in RGBA mode. (Color index lighting is described in section 2.13.5.)

Lighting is turned on or off using the generic `Enable` or `Disable` commands with the symbolic value `LIGHTING`. If lighting is off, the current color and current secondary color are assigned to the vertex primary and secondary color, respectively. If lighting is on, colors computed from the current lighting parameters are assigned to the vertex primary and secondary colors.

Lighting Operation

A lighting parameter is of one of five types: color, position, direction, real, or boolean. A color parameter consists of four floating-point values, one for each of R, G, B, and A, in that order. There are no restrictions on the allowable values for these parameters. A position parameter consists of four floating-point coordinates \((x, y, z, \text{ and } w)\) that specify a position in object coordinates \((w\) may be zero, indicating a point at infinity in the direction given by \(x, y, \text{ and } z\)). A direction parameter consists of three floating-point coordinates \((x, y, \text{ and } z)\) that specify a direction in object coordinates. A real parameter is one floating-point value. The various values and their types are summarized in table 2.11. The result of a lighting computation is undefined if a value for a parameter is specified that is outside the range given for that parameter in the table.

There are \(n\) light sources, indexed by \(i = 0, \ldots, n-1\). (\(n\) is an implementation-dependent maximum that must be at least 8.) Note that the default values for \(\text{d}_{\text{cli}}\) and \(\text{s}_{\text{cli}}\) differ for \(i = 0\) and \(i > 0\).

Before specifying the way that lighting computes colors, we introduce operators and notation that simplify the expressions involved. If \(c_1\) and \(c_2\) are colors without alpha where \(c_1 = (r_1, g_1, b_1)\) and \(c_2 = (r_2, g_2, b_2)\), then define \(c_1 * c_2 = (r_1r_2, g_1g_2, b_1b_2)\). Addition of colors is accomplished by addition of the components. Multiplication of colors by a scalar means multiplying each component by that scalar. If \(d_1\) and \(d_2\) are directions, then define

\[
d_1 \odot d_2 = \max\{d_1 \cdot d_2, 0\},
\]

(Directions are taken to have three coordinates.) If \(P_1\) and \(P_2\) are (homogeneous, with four coordinates) points then let \(\overrightarrow{P_1P_2}\) be the unit vector that points from \(P_1\) to \(P_2\).

Table 2.11: Summary of lighting parameters. The range of individual color components is \((-\infty, +\infty)\).
to $P_2$. Note that if $P_2$ has a zero $w$ coordinate and $P_1$ has non-zero $w$ coordinate, then $\overrightarrow{P_1P_2}$ is the unit vector corresponding to the direction specified by the $x$, $y$, and $z$ coordinates of $P_2$; if $P_1$ has a zero $w$ coordinate and $P_2$ has a non-zero $w$ coordinate then $\overrightarrow{P_1P_2}$ is the unit vector that is the negative of that corresponding to the direction specified by $P_1$. If both $P_1$ and $P_2$ have zero $w$ coordinates, then $\overrightarrow{P_1P_2}$ is the unit vector obtained by normalizing the direction corresponding to $P_2 - P_1$.

If $d$ is an arbitrary direction, then let $\hat{d}$ be the unit vector in $d$’s direction. Let $\|P_1P_2\|$ be the distance between $P_1$ and $P_2$. Finally, let $V$ be the point corresponding to the vertex being lit, and $n$ be the corresponding normal. Let $P_e$ be the eyepoint ($(0, 0, 0, 1)$ in eye coordinates).

Lighting produces two colors at a vertex: a primary color $c_{pri}$ and a secondary color $c_{sec}$. The values of $c_{pri}$ and $c_{sec}$ depend on the light model color control, $c_{es}$. If $c_{es} = \text{SINGLE\_COLOR}$, then the equations to compute $c_{pri}$ and $c_{sec}$ are

$$
c_{pri} = e_{cm} + a_{cm} \cdot a_{cs} + \sum_{i=0}^{n-1} (att_i)(spot_i)[a_{cm} \cdot a_{cli} + (n \odot \overrightarrow{VP_{pli}})d_{cm} \cdot d_{cli} + (f_i)(n \odot \hat{h}_i)s_{rm} s_{cm} \cdot s_{cli}]
$$

$$
c_{sec} = (0, 0, 0, 1)
$$

If $c_{es} = \text{SEPARATE\_SPECULAR\_COLOR}$, then

$$
c_{pri} = e_{cm} + a_{cm} \cdot a_{cs} + \sum_{i=0}^{n-1} (att_i)(spot_i)[a_{cm} \cdot a_{cli} + (n \odot \overrightarrow{VP_{pli}})d_{cm} \cdot d_{cli}]
$$

$$
c_{sec} = \sum_{i=0}^{n-1} (att_i)(spot_i)(f_i)(n \odot \hat{h}_i)s_{rm} s_{cm} \cdot s_{cli}
$$
where

\[ f_i = \begin{cases} 
1, & \n \odot \overrightarrow{VP_{pli}} \neq 0, \\
0, & \text{otherwise}, 
\end{cases} \quad (2.8) \]

\[ h_i = \begin{cases} 
\overrightarrow{VP_{pli}} + \overrightarrow{VP_e}, & v_{bs} = \text{TRUE}, \\
\overrightarrow{VP_{pli}} + (0 \ 0 \ 1)^T, & v_{bs} = \text{FALSE}, 
\end{cases} \quad (2.9) \]

\[ att_i = \begin{cases} 
\frac{1}{k_{0i} + k_{1i}||\overrightarrow{VP_{pli}}|| + k_{2i}||\overrightarrow{VP_{pli}}||^2}, & \text{if } \overrightarrow{P_{pli}} \text{'s } w \neq 0, \\
1.0, & \text{otherwise.} 
\end{cases} \quad (2.10) \]

\[ spot_i = \begin{cases} 
(\overrightarrow{P_{pli}} \odot \hat{s}_{dli})_{s_{ri}}, & c_{r_{ti}} \neq 180.0, \overrightarrow{P_{pli}} \odot \hat{s}_{dli} \geq \cos(c_{r_{ti}}), \\
0.0, & c_{r_{ti}} \neq 180.0, \overrightarrow{P_{pli}} \odot \hat{s}_{dli} < \cos(c_{r_{ti}}), \\
1.0, & c_{r_{ti}} = 180.0. 
\end{cases} \quad (2.11) \]

All computations are carried out in eye coordinates.

The value of A produced by lighting is the alpha value associated with \( d_{cm} \). A is always associated with the primary color \( c_{pri} \); the alpha component of \( c_{sec} \) is always 1.

Results of lighting are undefined if the \( w_e \) coordinate (\( w \) in eye coordinates) of \( V \) is zero.

Lighting may operate in two-sided mode (\( t_{bs} = \text{TRUE} \)), in which a front color is computed with one set of material parameters (the front material) and a back color is computed with a second set of material parameters (the back material). This second computation replaces \( n \) with \(-n\). If \( t_{bs} = \text{FALSE} \), then the back color and front color are both assigned the color computed using the front material with \( n \).

Additionally, vertex and geometry shaders can operate in two-sided color mode. When a vertex or geometry shader is active, front and back colors can be computed by the shader and written to the \text{gl\_FrontColor}, \text{gl\_BackColor}, \text{gl\_FrontSecondaryColor} and \text{gl\_BackSecondaryColor} outputs. If \text{VERTEX\_PROGRAM\_TWO\_SIDE} is enabled, the GL chooses between front and back colors, as described below. Otherwise, the front color output is always...
selected. Two-sided color mode is enabled and disabled by calling \texttt{Enable} or \texttt{Disable} with the symbolic value \texttt{VERTEXPROGRAM\_TWO\_SIDE}.

The selection between back and front colors depends on the primitive of which the vertex being lit is a part. If the primitive is a point or a line segment, the front color is always selected. If it is a polygon, then the selection is performed based on the sign of the (clipped or unclipped) polygon's area $a$ computed in window coordinates, as described in equation 3.8 of section 3.6.1. If the sign of $a$ (including the possible reversal of this sign as indicated by the last call to \texttt{FrontFace}) is positive, the color of each vertex of the polygon becomes the front color computed for that vertex; otherwise the back color is selected.

\subsection*{2.13.2 Lighting Parameter Specification}

Lighting parameters are divided into three categories: material parameters, light source parameters, and lighting model parameters (see table 2.11). Sets of lighting parameters are specified with

\begin{verbatim}
void Material[if](enum face, enum pname, T param );
void Material[if]*v( enum face, enum pname, T params );
void Light[if](enum light, enum pname, T param );
void Light[if]*v( enum light, enum pname, T params );
void LightModel[if]( enum pname, T param );
void LightModel[if]*v( enum pname, T params );
\end{verbatim}

\texttt{pname} is a symbolic constant indicating which parameter is to be set (see table 2.12). In the vector versions of the commands, \texttt{params} is a pointer to a group of values to which to set the indicated parameter. The number of values pointed to depends on the parameter being set. In the non-vector versions, \texttt{param} is a value to which to set a single-valued parameter. (If \texttt{param} corresponds to a multi-valued parameter, the error \texttt{INVALID\_ENUM} results.) For the \texttt{Material} command, \texttt{face} must be one of \texttt{FRONT}, \texttt{BACK}, or \texttt{FRONT\_AND\_BACK}, indicating that the property \texttt{name} of the front or back material, or both, respectively, should be set. In the case of \texttt{Light}, \texttt{light} is a symbolic constant of the form \texttt{LIGHT\_i}, indicating that light $i$ is to have the specified parameter set. The constants obey $\texttt{LIGHT\_i} = \texttt{LIGHT\_0} + i$.

Table 2.12 gives, for each of the three parameter groups, the correspondence between the pre-defined constant names and their names in the lighting equations, along with the number of values that must be specified with each. Color parameters specified with \texttt{Material} and \texttt{Light} are converted to floating-point values (if specified as integers) as described in equation 2.2. The error \texttt{INVALID\_VALUE} occurs if a specified lighting parameter lies outside the allowable range given in
Material properties can be changed inside a Begin/End pair by calling Material. However, when a vertex shader is active such property changes are not guaranteed to update material parameters, defined in table 2.12, until the following End command.

The current model-view matrix is applied to the position parameter indicated with Light for a particular light source when that position is specified. These transformed values are the values used in the lighting equation.

The spotlight direction is transformed when it is specified using only the upper leftmost 3x3 portion of the model-view matrix. That is, if $M_u$ is the upper left 3x3 matrix taken from the current model-view matrix $M$, then the spotlight direction

$$\begin{bmatrix}
  d_x \\
  d_y \\
  d_z
\end{bmatrix}
$$

is transformed to

$$\begin{bmatrix}
  d'_x \\
  d'_y \\
  d'_z
\end{bmatrix} = M_u \begin{bmatrix}
  d_x \\
  d_y \\
  d_z
\end{bmatrix}.$$

An individual light is enabled or disabled by calling Enable or Disable with the symbolic value LIGHT$i$ ($i$ is in the range $0$ to $n - 1$, where $n$ is the implementation-dependent number of lights). If light $i$ is disabled, the $i$th term in the lighting equation is effectively removed from the summation.

### 2.13.3 ColorMaterial

It is possible to attach one or more material properties to the current color, so that they continuously track its component values. This behavior is enabled and disabled by calling Enable or Disable with the symbolic value COLOR_MATERIAL.

The command that controls which of these modes is selected is

```c
void ColorMaterial( enum face, enum mode );
```

*face* is one of FRONT, BACK, or FRONT_AND_BACK, indicating whether the front material, back material, or both are affected by the current color. *mode* is one of EMISSION, AMBIENT, DIFFUSE, SPECULAR, or AMBIENT_AND_DIFFUSE and specifies which material property or properties track the current color. If *mode* is EMISSION, AMBIENT, DIFFUSE, or SPECULAR, then the value of $e_{cm}$, $a_{cm}$, $d_{cm}$, or $s_{cm}$, respectively, will track the current color. If *mode* is AMBIENT_AND_DIFFUSE, both $a_{cm}$ and $d_{cm}$ track the current color. The replacements made to

AMBIENT_AND_DIFFUSE is used to set \( a_{cm} \) and \( d_{cm} \) to the same value.
2.13. FIXED-FUNCTION VERTEX LIGHTING AND COLORING

Figure 2.12. **ColorMaterial** operation. Material properties are continuously updated from the current color while **ColorMaterial** is enabled and has the appropriate mode. Only the front material properties are included in this figure. The back material properties are treated identically, except that *face* must be **BACK** or **FRONT AND BACK**.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.13. FIXED-FUNCTION VERTEX LIGHTING AND COLORING

Material properties are permanent; the replaced values remain until changed by either sending a new color or by setting a new material value when \texttt{ColorMaterial} is not currently enabled to override that particular value. When \texttt{COLOR_MATERIAL} is enabled, the indicated parameter or parameters always track the current color. For instance, calling

\texttt{ColorMaterial}(\texttt{FRONT, AMBIENT})

while \texttt{COLOR_MATERIAL} is enabled sets the front material $a_{cm}$ to the value of the current color.

Material properties can be changed inside a \texttt{Begin/End} pair indirectly by enabling \texttt{ColorMaterial} mode and making \texttt{Color} calls. However, when a vertex shader is active such property changes are not guaranteed to update material parameters, defined in table 2.12, until the following \texttt{End} command.

2.13.4 Lighting State

The state required for lighting consists of all of the lighting parameters (front and back material parameters, lighting model parameters, and at least 8 sets of light parameters), a bit indicating whether a back color distinct from the front color should be computed, at least 8 bits to indicate which lights are enabled, a five-valued variable indicating the current \texttt{ColorMaterial} mode, a bit indicating whether or not \texttt{COLOR_MATERIAL} is enabled, and a single bit to indicate whether lighting is enabled or disabled. In the initial state, all lighting parameters have their default values. Back color evaluation does not take place, \texttt{ColorMaterial} is \texttt{FRONT_AND_BACK} and \texttt{AMBIENT_AND_DIFFUSE}, and both lighting and \texttt{COLOR_MATERIAL} are disabled.

2.13.5 Color Index Lighting

A simplified lighting computation applies in color index mode that uses many of the parameters controlling RGBA lighting, but none of the RGBA material parameters. First, the RGBA diffuse and specular intensities of light $i$ ($d_{cli}$ and $s_{cli}$, respectively) determine color index diffuse and specular light intensities, $d_{li}$ and $s_{li}$ from

\[
d_{li} = (.30)R(d_{cli}) + (.59)G(d_{cli}) + (.11)B(d_{cli})
\]

and

\[
s_{li} = (.30)R(s_{cli}) + (.59)G(s_{cli}) + (.11)B(s_{cli}).
\]

$R(x)$ indicates the R component of the color $x$ and similarly for $G(x)$ and $B(x)$. 

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
Next, let
\[ s = \sum_{i=0}^{n} (\text{att}_i)(\text{spot}_i)(s_i)(f_i)(\mathbf{n} \odot \hat{h}_i)^{a_{rm}} \]
where \( \text{att}_i \) and \( \text{spot}_i \) are given by equations 2.10 and 2.11, respectively, and \( f_i \) and \( \hat{h}_i \) are given by equations 2.8 and 2.9, respectively. Let \( s' = \min\{s, 1\} \). Finally, let
\[ d = \sum_{i=0}^{n} (\text{att}_i)(\text{spot}_i)(d_i)(\mathbf{n} \odot \hat{VP}_{pli}). \]
Then color index lighting produces a value \( c \), given by
\[ c = a_m + d(1 - s')(d_m - a_m) + s'(s_m - a_m). \]
The final color index is
\[ c' = \min\{c, s_m\}. \]
The values \( a_m, d_m, \) and \( s_m \) are material properties described in tables 2.11 and 2.12. Any ambient light intensities are incorporated into \( a_m \). As with RGBA lighting, disabled lights cause the corresponding terms from the summations to be omitted. The interpretation of \( t_{ba} \) and the calculation of front and back colors is carried out as has already been described for RGBA lighting.

The values \( a_m, d_m, \) and \( s_m \) are set with Material using a pname of COLOR_INDEXES. Their initial values are 0, 1, and 1, respectively. The additional state consists of three floating-point values. These values have no effect on RGBA lighting.

### 2.13.6 Clamping or Masking

When the GL is in RGBA mode and vertex color clamping is enabled, all components of both primary and secondary colors are clamped to the range \([0, 1]\) after lighting. If color clamping is disabled, the primary and secondary colors are unmodified. Vertex color clamping is controlled by calling ClampColor, as described in section 3.7.5, with a target of CLAMP_VERTEX_COLOR.

For a color index, the index is first converted to fixed-point with an unspecified number of bits to the right of the binary point; the nearest fixed-point value is selected. Then, the bits to the right of the binary point are left alone while the integer portion is masked (bitwise ANDed) with \( 2^n - 1 \), where \( n \) is the number of bits in a color in the color index buffer (buffers are discussed in chapter 4).

The state required for vertex color clamping is a three-valued integer, initially set to TRUE.
2.14 Vertex Shaders

The sequence of operations described in sections 2.12 through 2.13 is a fixed-function method for processing vertex data. Applications can also use vertex shaders to describe the operations that occur on vertex values and their associated data.

A vertex shader is an array of strings containing source code for the operations that are meant to occur on each vertex that is processed. The language used for vertex shaders is described in the OpenGL Shading Language Specification.

To use a vertex shader, shader source code is first loaded into a shader object and then compiled. One or more vertex shader objects are then attached to a program object. A program object is then linked, which generates executable code from all the compiled shader objects attached to the program. When a linked program object is used as the current program object, the executable code for the vertex shaders it contains is used to process vertices.

In addition to vertex shaders, geometry shaders and fragment shaders can be created, compiled, and linked into program objects. Geometry shaders affect the processing of primitives assembled from vertices (see section 2.15). Fragment shaders affect the processing of fragments during rasterization (see section 3.12). A single program object can contain all of vertex, geometry, and fragment shaders.

When the program object currently in use includes a vertex shader, its vertex shader is considered active and is used to process vertices. If the program object has no vertex shader, or no program object is currently in use, the fixed-function method for processing vertices is used instead.

A vertex shader can reference a number of variables as it executes. Vertex attributes are the per-vertex values specified in section 2.7. Uniforms are per-program variables that are constant during program execution. Samplers are a special form of uniform used for texturing (section 3.9). Varying variables hold the results of vertex shader execution that are used later in the pipeline. Each of these variable types is described in more detail below.

2.14.1 Shader Objects

The source code that makes up a program that gets executed by one of the programmable stages is encapsulated in one or more shader objects.

The name space for shader objects is the unsigned integers, with zero reserved for the GL. This name space is shared with program objects. The following sections define commands that operate on shader and program objects by name. Commands that accept shader or program object names will generate the error INVALID_VALUE if the provided name is not the name of either a shader or program object.
and INVALID_OPERATION if the provided name identifies an object that is not the expected type.

To create a shader object, use the command

```c
uint CreateShader( enum type );
```

The shader object is empty when it is created. The `type` argument specifies the type of shader object to be created. For vertex shaders, `type` must be VERTEX_SHADER. A non-zero name that can be used to reference the shader object is returned. If an error occurs, zero will be returned.

The command

```c
void ShaderSource( uint shader, sizei count, const char **string, const int *length );
```

loads source code into the shader object named `shader`. `string` is an array of `count` pointers to optionally null-terminated character strings that make up the source code. The `length` argument is an array with the number of `chars` in each string (the string length). If an element in `length` is negative, its accompanying string is null-terminated. If `length` is NULL, all strings in the `string` argument are considered null-terminated. The `ShaderSource` command sets the source code for the `shader` to the text strings in the `string` array. If `shader` previously had source code loaded into it, the existing source code is completely replaced. Any length passed in excludes the null terminator in its count.

The strings that are loaded into a shader object are expected to form the source code for a valid shader as defined in the OpenGL Shading Language Specification.

Once the source code for a shader has been loaded, a shader object can be compiled with the command

```c
void CompileShader( uint shader );
```

Each shader object has a boolean status, COMPILIE_STATUS, that is modified as a result of compilation. This status can be queried with `GetShaderiv` (see section 6.1.16). This status will be set to TRUE if `shader` was compiled without errors and is ready for use, and FALSE otherwise. Compilation can fail for a variety of reasons as listed in the OpenGL Shading Language Specification. If `CompileShader` failed, any information about a previous compile is lost. Thus a failed compile does not restore the old state of `shader`.

Changing the source code of a shader object with `ShaderSource` does not change its compile status or the compiled shader code.
2.14. VERTEX SHADERS

Each shader object has an information log, which is a text string that is overwritten as a result of compilation. This information log can be queried with \texttt{GetShaderInfoLog} to obtain more information about the compilation attempt (see section 6.1.16).

Shader objects can be deleted with the command

\begin{verbatim}
void DeleteShader( uint shader );
\end{verbatim}

If \textit{shader} is not attached to any program object, it is deleted immediately. Otherwise, \textit{shader} is flagged for deletion and will be deleted when it is no longer attached to any program object. If an object is flagged for deletion, its boolean status bit \texttt{DELETE\_STATUS} is set to true. The value of \texttt{DELETE\_STATUS} can be queried with \texttt{GetShaderiv} (see section 6.1.16). \texttt{DeleteShader} will silently ignore the value zero.

2.14.2 Program Objects

The shader objects that are to be used by the programmable stages of the GL are collected together to form a \textit{program object}. The programs that are executed by these programmable stages are called \textit{executables}. All information necessary for defining an executable is encapsulated in a program object. A program object is created with the command

\begin{verbatim}
uint CreateProgram( void );
\end{verbatim}

Program objects are empty when they are created. A non-zero name that can be used to reference the program object is returned. If an error occurs, zero will be returned.

To attach a shader object to a program object, use the command

\begin{verbatim}
void AttachShader( uint program, uint shader );
\end{verbatim}

The error \texttt{INVALID\_OPERATION} is generated if \textit{shader} is already attached to \textit{program}.

Shader objects may be attached to program objects before source code has been loaded into the shader object, or before the shader object has been compiled. Multiple shader objects of the same type may be attached to a single program object, and a single shader object may be attached to more than one program object.

To detach a shader object from a program object, use the command

\begin{verbatim}
void DetachShader( uint program, uint shader );
\end{verbatim}
The error INVALID_OPERATION is generated if shader is not attached to program. If shader has been flagged for deletion and is not attached to any other program object, it is deleted.

In order to use the shader objects contained in a program object, the program object must be linked. The command

```c
void LinkProgram(uint program);
```

will link the program object named program. Each program object has a boolean status, LINK_STATUS, that is modified as a result of linking. This status can be queried with GetProgramiv (see section 6.1.16). This status will be set to TRUE if a valid executable is created, and FALSE otherwise. Linking can fail for a variety of reasons as specified in the OpenGL Shading Language Specification. Linking will also fail if one or more of the shader objects, attached to program are not compiled successfully, or if more active uniform or active sampler variables are used in program than allowed (see sections 2.14.4, 2.14.5, and 2.15.3).

Linking will also fail if the program object contains objects to form a geometry shader (see section 2.15), and

- the program contains no objects to form a vertex shader;
- the input primitive type, output primitive type, or maximum output vertex count is not specified in any compiled geometry shader object; or
- the input primitive type, output primitive type, or maximum output vertex count is specified differently in multiple geometry shader objects.

If LinkProgram failed, any information about a previous link of that program object is lost. Thus, a failed link does not restore the old state of program.

Each program object has an information log that is overwritten as a result of a link operation. This information log can be queried with GetProgramInfoLog to obtain more information about the link operation or the validation information (see section 6.1.16).

If a valid executable is created, it can be made part of the current rendering state with the command

```c
void UseProgram(uint program);
```

This command will install the executable code as part of current rendering state if the program object program contains valid executable code, i.e. has been linked successfully. If UseProgram is called with program set to 0, it is as if the GL
had no programmable stages and the fixed-function paths will be used instead. If program has not been successfully linked, the error INVALID_OPERATION is generated and the current rendering state is not modified.

While a program object is in use, applications are free to modify attached shader objects, compile attached shader objects, attach additional shader objects, and detach shader objects. These operations do not affect the link status or executable code of the program object.

If the program object that is in use is re-linked successfully, the LinkProgram command will install the generated executable code as part of the current rendering state if the specified program object was already in use as a result of a previous call to UseProgram.

If that program object that is in use is re-linked unsuccessfully, the link status will be set to FALSE, but existing executable and associated state will remain part of the current rendering state until a subsequent call to UseProgram removes it from use. After such a program is removed from use, it can not be made part of the current rendering state until it is successfully re-linked.

Program objects can be deleted with the command

```c
void DeleteProgram( uint program );
```

If program is not the current program for any GL context, it is deleted immediately. Otherwise, program is flagged for deletion and will be deleted when it is no longer the current program for any context. When a program object is deleted, all shader objects attached to it are detached. DeleteProgram will silently ignore the value zero.

### 2.14.3 Vertex Attributes

Vertex shaders can access built-in vertex attribute variables corresponding to the per-vertex state set by commands such as Vertex, Normal, and Color. Vertex shaders can also define named attribute variables, which are bound to the generic vertex attributes that are set by VertexAttrib*. This binding can be specified by the application before the program is linked, or automatically assigned by the GL when the program is linked.

When an attribute variable declared as a float, vec2, vec3 or vec4 is bound to a generic attribute index \( i \), its value(s) are taken from the \( x \), \( (x, y) \), \( (x, y, z) \), or \( (x, y, z, w) \) components, respectively, of the generic attribute \( i \). When an attribute variable is declared as a mat2, mat3x2 or mat4x2, its matrix columns are taken from the \( (x, y) \) components of generic attributes \( i \) and \( i + 1 \) (mat2), from attributes \( i \) through \( i + 2 \) (mat3x2), or from attributes \( i \) through \( i + 3 \) (mat4x2). When an
attribute variable is declared as a mat2x3, mat3 or mat4x3, its matrix columns are taken from the (x, y, z) components of generic attributes i and i + 1 (mat2x3), from attributes i through i + 2 (mat3), or from attributes i through i + 3 (mat4x3). When an attribute variable is declared as a mat2x4, mat3x4 or mat4, its matrix columns are taken from the (x, y, z, w) components of generic attributes i and i + 1 (mat2x4), from attributes i through i + 2 (mat3x4), or from attributes i through i + 3 (mat4).

An attribute variable (either conventional or generic) is considered active if it is determined by the compiler and linker that the attribute may be accessed when the shader is executed. Attribute variables that are declared in a vertex shader but never used will not count against the limit. In cases where the compiler and linker cannot make a conclusive determination, an attribute will be considered active. A program object will fail to link if the sum of the active generic and active conventional attributes exceeds MAX_VERTEX_ATTRIBS.

To determine the set of active vertex attributes used by a program, and to determine their types, use the command:

```c
void GetActiveAttrib(uint program, uint index,
    sizei bufSize, sizei *length, int *size, enum *type,
    char *name);
```

This command provides information about the attribute selected by index. An index of 0 selects the first active attribute, and an index of ACTIVE_ATTRIBUTES − 1 selects the last active attribute. The value of ACTIVE_ATTRIBUTES can be queried with GetProgramiv (see section 6.1.16). If index is greater than or equal to ACTIVE_ATTRIBUTES, the error INVALID_VALUE is generated. Note that index simply identifies a member in a list of active attributes, and has no relation to the generic attribute that the corresponding variable is bound to.

The parameter program is the name of a program object for which the command LinkProgram has been issued in the past. It is not necessary for program to have been linked successfully. The link could have failed because the number of active attributes exceeded the limit.

The name of the selected attribute is returned as a null-terminated string in name. The actual number of characters written into name, excluding the null terminator, is returned in length. If length is NULL, no length is returned. The maximum number of characters that may be written into name, including the null terminator, is specified by bufSize. The returned attribute name can be the name of a generic attribute or a conventional attribute (which begin with the prefix "gl_", see the OpenGL Shading Language Specification for a complete list). The length of the longest attribute name in program is given by ACTIVE_ATTRIBUTE_MAX_LENGTH, which can be queried with GetProgramiv (see section 6.1.16).
For the selected attribute, the type of the attribute is returned into `type`. The size of the attribute is returned into `size`. The value in `size` is in units of the type returned in `type`. The type returned can be any of `FLOAT`, `FLOAT_VEC2`, `FLOAT_VEC3`, `FLOAT_VEC4`, `FLOAT_MAT2`, `FLOAT_MAT3`, `FLOAT_MAT4`, `FLOAT_MAT2x3`, `FLOAT_MAT2x4`, `FLOAT_MAT3x2`, `FLOAT_MAT3x4`, `FLOAT_MAT4x2`, `FLOAT_MAT4x3`, `INT`, `INT_VEC2`, `INT_VEC3`, `INT_VEC4`, `UNSIGNED_INT`, `UNSIGNED_INT_VEC2`, `UNSIGNED_INT_VEC3`, or `UNSIGNED_INT_VEC4`.

If an error occurred, the return parameters `length`, `size`, `type` and `name` will be unmodified.

This command will return as much information about active attributes as possible. If no information is available, `length` will be set to zero and `name` will be an empty string. This situation could arise if `GetActiveAttrib` is issued after a failed link.

After a program object has been linked successfully, the bindings of attribute variable names to indices can be queried. The command

```c
int GetAttribLocation(uint program, const char *name);
```

returns the generic attribute index that the attribute variable named `name` was bound to when the program object named `program` was last linked. `name` must be a null-terminated string. If `name` is active and is an attribute matrix, `GetAttribLocation` returns the index of the first column of that matrix. If `program` has not been successfully linked, the error `INVALID_OPERATION` is generated. If `name` is not an active attribute, if `name` is a conventional attribute, or if an error occurs, -1 will be returned.

The binding of an attribute variable to a generic attribute index can also be specified explicitly. The command

```c
void BindAttribLocation(uint program, uint index, const char *name);
```

specifies that the attribute variable named `name` in program `program` should be bound to generic vertex attribute `index` when the program is next linked. If `name` was bound previously, its assigned binding is replaced with `index`. `name` must be a null-terminated string. The error `INVALID_VALUE` is generated if `index` is equal or greater than `MAX_VERTEX_ATTRIBS`. `BindAttribLocation` has no effect until the program is linked. In particular, it doesn’t modify the bindings of active attribute variables in a program that has already been linked.

Built-in attribute variables are automatically bound to conventional attributes, and cannot have an assigned binding. The error `INVALID_OPERATION` is generated if `name` starts with the reserved "gl_" prefix.
2.14. VERTEX SHADERS

When a program is linked, any active attributes without a binding specified through `BindAttribLocation` will automatically be bound to vertex attributes by the GL. Such bindings can be queried using the command `GetAttribLocation`. `LinkProgram` will fail if the assigned binding of an active attribute variable would cause the GL to reference a non-existent generic attribute (one greater than or equal to `MAX_VERTEX_ATTRIBS`). `LinkProgram` will fail if the attribute bindings assigned by `BindAttribLocation` do not leave not enough space to assign a location for an active matrix attribute, which requires multiple contiguous generic attributes. `LinkProgram` will also fail if the vertex shaders used in the program object contain assignments (not removed during pre-processing) to an attribute variable bound to generic attribute zero and to the conventional vertex position (`gl_Vertex`).

`BindAttribLocation` may be issued before any vertex shader objects are attached to a program object. Hence it is allowed to bind any name (except a name starting with "gl_.") to an index, including a name that is never used as an attribute in any vertex shader object. Assigned bindings for attribute variables that do not exist or are not active are ignored.

The values of generic attributes sent to generic attribute index $i$ are part of current state, just like the conventional attributes. If a new program object has been made active, then these values will be tracked by the GL in such a way that the same values will be observed by attributes in the new program object that are also bound to index $i$.

It is possible for an application to bind more than one attribute name to the same location. This is referred to as aliasing. This will only work if only one of the aliased attributes is active in the executable program, or if no path through the shader consumes more than one attribute of a set of attributes aliased to the same location. A link error can occur if the linker determines that every path through the shader consumes multiple aliased attributes, but implementations are not required to generate an error in this case. The compiler and linker are allowed to assume that no aliasing is done, and may employ optimizations that work only in the absence of aliasing. It is not possible to alias generic attributes with conventional ones.

2.14.4 Uniform Variables

Shaders can declare named uniform variables, as described in the OpenGL Shading Language Specification. Values for these uniforms are constant over a primitive, and typically they are constant across many primitives. Uniforms are program object-specific state. They retain their values once loaded, and their values are restored whenever a program object is used, as long as the program object has not been re-linked. A uniform is considered active if it is determined by the compiler and linker that the uniform will actually be accessed when the executable code
is executed. In cases where the compiler and linker cannot make a conclusive determination, the uniform will be considered active.

Sets of uniforms can be grouped into *uniform blocks*. The values of each uniform in such a set are extracted from the data store of a buffer object corresponding to the uniform block. OpenGL Shading Language syntax serves to delimit named blocks of uniforms that can be backed by a buffer object. These are referred to as *named uniform blocks*, and are assigned a *uniform block index*. Uniforms that are declared outside of a named uniform block are said to be part of the *default uniform block*. Default uniform blocks have no name or uniform block index. Like uniforms, uniform blocks can be active or inactive. Active uniform blocks are those that contain active uniforms after a program has been compiled and linked.

The amount of storage available for uniform variables in the default uniform block accessed by a vertex shader is specified by the value of the implementation-dependent constant `MAX_VERTEX_UNIFORM_COMPONENTS`. The total amount of combined storage available for uniform variables in all uniform blocks accessed by a vertex shader (including the default uniform block) is specified by the value of the implementation-dependent constant `MAX_COMBINED_VERTEX_UNIFORM_COMPONENTS`. These values represent the numbers of individual floating-point, integer, or boolean values that can be held in uniform variable storage for a vertex shader. A link error is generated if an attempt is made to utilize more than the space available for vertex shader uniform variables.

When a program is successfully linked, all active uniforms belonging to the program object’s default uniform block are initialized as defined by the version of the OpenGL Shading Language used to compile the program. A successful link will also generate a location for each active uniform in the default uniform block. The values of active uniforms in the default uniform block can be changed using this location and the appropriate `Uniform*` command (see below). These locations are invalidated and new ones assigned after each successful re-link.

Similarly, when a program is successfully linked, all active uniforms belonging to the program’s named uniform blocks are assigned offsets (and strides for array and matrix type uniforms) within the uniform block according to layout rules described below. Uniform buffer objects provide the storage for named uniform blocks, so the values of active uniforms in named uniform blocks may be changed by modifying the contents of the buffer object using commands such as `BufferData`, `BufferSubData`, `MapBuffer`, and `UnmapBuffer`. Uniforms in a named uniform block are not assigned a location and may not be modified using the `Uniform*` commands. The offsets and strides of all active uniforms belonging to named uniform blocks of a program object are invalidated and new ones assigned after each successful re-link.

To find the location within a program object of an active uniform variable as-
sociated with the default uniform block, use the command

```c
int GetUniformLocation(uint program, const char *name);
```

This command will return the location of uniform variable `name` if it is associated with the default uniform block. `name` must be a null-terminated string, without white space. The value -1 will be returned if `name` starts with the reserved prefix "gl_", if `name` does not correspond to an active uniform variable name in `program`, or if `name` is associated with a named uniform block.

If `program` has not been successfully linked, the error INVALID_OPERATION is generated. After a program is linked, the location of a uniform variable will not change, unless the program is re-linked.

A valid `name` cannot be a structure, an array of structures, or any portion of a single vector or a matrix. In order to identify a valid `name`, the "." (dot) and "[ ]" operators can be used in `name` to specify a member of a structure or element of an array.

The first element of a uniform array is identified using the name of the uniform array appended with "[0]". Except if the last part of the string `name` indicates a uniform array, then the location of the first element of that array can be retrieved by either using the name of the uniform array, or the name of the uniform array appended with "[0]".

Named uniform blocks, like uniforms, are identified by name strings. Uniform block indices corresponding to uniform block names can be queried by calling

```c
uint GetUniformBlockIndex(uint program, const char *uniformBlockName);
```

`program` is the name of a program object for which the command LinkProgram has been issued in the past. It is not necessary for `program` to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

`uniformBlockName` must contain a null-terminated string specifying the name of a uniform block.

GetUniformBlockIndex returns the uniform block index for the uniform block named `uniformBlockName` of `program`. If `uniformBlockName` does not identify an active uniform block of `program`, or an error occurred, then INVALID_INDEX is returned. The indices of the active uniform blocks of a program are assigned in consecutive order, beginning with zero.

An active uniform block’s name string can be queried from its uniform block index by calling
2.14. VERTEX SHADERS

```c
void GetActiveUniformBlockName( uint program,
                                 uint uniformBlockIndex, sizei bufSize, sizei *length,
                                 char *uniformBlockName );
```

**program** is the name of a program object for which the command **LinkProgram** has been issued in the past. It is not necessary for **program** to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

**uniformBlockIndex** must be an active uniform block index of **program**, in the range zero to the value of **ACTIVE_UNIFORM_BLOCKS** - 1. The value of **ACTIVE_UNIFORM_BLOCKS** can be queried with **GetProgramiv** (see section 6.1.16). If **uniformBlockIndex** is greater than or equal to the value of **ACTIVE_UNIFORM_BLOCKS**, the error **INVALID_VALUE** is generated.

The string name of the uniform block identified by **uniformBlockIndex** is returned into **uniformBlockName**. The name is null-terminated. The actual number of characters written into **uniformBlockName**, excluding the null terminator, is returned in **length**. If **length** is **NULL**, no length is returned.

**bufSize** contains the maximum number of characters (including the null terminator) that will be written back to **uniformBlockName**.

If an error occurs, nothing will be written to **uniformBlockName** or **length**.

Information about an active uniform block can be queried by calling

```c
void GetActiveUniformBlockiv( uint program,
                              uint uniformBlockIndex, enum pname, int *params );
```

**program** is the name of a program object for which the command **LinkProgram** has been issued in the past. It is not necessary for **program** to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

**uniformBlockIndex** is an active uniform block index of **program**. If **uniformBlockIndex** is greater than or equal to the value of **ACTIVE_UNIFORM_BLOCKS**, or is not the index of an active uniform block in **program**, the error **INVALID_VALUE** is generated.

If no error occurs, the uniform block parameter(s) specified by **pname** are returned in **params**. Otherwise, nothing will be written to **params**.

If **pname** is **UNIFORM_BLOCK_BINDING**, then the index of the uniform buffer binding point last selected by the uniform block specified by **uniformBlockIndex** for **program** is returned. If no uniform block has been previously specified, zero is returned.

If **pname** is **UNIFORM_BLOCK_DATA_SIZE**, then the implementation-dependent minimum total buffer object size, in basic machine units, required to...
hold all active uniforms in the uniform block identified by $\text{uniformBlockIndex}$ is returned. It is neither guaranteed nor expected that a given implementation will arrange uniform values as tightly packed in a buffer object. The exception to this is the std140 uniform block layout, which guarantees specific packing behavior and does not require the application to query for offsets and strides. In this case the minimum size may still be queried, even though it is determined in advance based only on the uniform block declaration (see “Standard Uniform Block Layout” in section 2.14.4).

The total amount of buffer object storage available for any given uniform block is subject to an implementation-dependent limit. The maximum amount of available space, in basic machine units, can be queried by calling GetIntegerfv with the constant MAX_UNIFORM_BLOCK_SIZE. If the amount of storage required for a uniform block exceeds this limit, a program may fail to link.

If $\text{pname}$ is UNIFORM_BLOCK_NAME_LENGTH, then the total length (including the null terminator) of the name of the uniform block identified by $\text{uniformBlockIndex}$ is returned.

If $\text{pname}$ is UNIFORM_BLOCK_ACTIVE_UNIFORMS, then the number of active uniforms in the uniform block identified by $\text{uniformBlockIndex}$ is returned.

If $\text{pname}$ is UNIFORM_BLOCK_ACTIVE_UNIFORM_INDICES, then a list of the active uniform indices for the uniform block identified by $\text{uniformBlockIndex}$ is returned. The number of elements that will be written to $\text{params}$ is the value of UNIFORM_BLOCK_ACTIVE_UNIFORMS for $\text{uniformBlockIndex}$.

If $\text{pname}$ is UNIFORM_BLOCK_REFERENCED_BY_VERTEX_SHADER, UNIFORM_BLOCK_REFERENCED_BY_GEOMETRY_SHADER, or UNIFORM_BLOCK_REFERENCED_BY_FRAGMENT_SHADER, then a boolean value indicating whether the uniform block identified by $\text{uniformBlockIndex}$ is referenced by the vertex, geometry, or fragment programming stages of $\text{program}$, respectively, is returned.

Each active uniform, whether in a named uniform block or in the default block, is assigned an index when a program is linked. Indices are assigned in consecutive order, beginning with zero. The indices assigned to a set of uniforms in a program may be queried by calling

```c
void GetUniformIndices( uint program,
   sizei uniformCount, const char **uniformNames,
   uint *uniformIndices );
```

$\text{program}$ is the name of a program object for which the command LinkProgram has been issued in the past. It is not necessary for $\text{program}$ to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
uniformCount indicates both the number of elements in the array of names uniformNames and the number of indices that may be written to uniformIndices.

uniformNames contains a list of uniformCount name strings identifying the uniform names to be queried for indices. For each name string in uniformNames, the index assigned to the active uniform of that name will be written to the corresponding element of uniformIndices. If a string in uniformNames is not the name of an active uniform, the value INVALID_INDEX will be written to the corresponding element of uniformIndices.

If an error occurs, nothing is written to uniformIndices.

The name of an active uniform may be queried from the corresponding uniform index by calling

```c
void GetActiveUniformName( uint program,
                             uint uniformIndex, sizei bufSize, sizei *length,
                             char *uniformName );
```

program is the name of a program object for which the command LinkProgram has been issued in the past. It is not necessary for program to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

uniformIndex must be an active uniform index of the program program, in the range zero to the value of ACTIVE_UNIFORMS - 1. The value of ACTIVE_UNIFORMS can be queried with GetProgramiv. If uniformIndex is greater than or equal to the value of ACTIVE_UNIFORMS, the error INVALID_VALUE is generated.

The name of the uniform identified by uniformIndex is returned as a null-terminated string in uniformName. The actual number of characters written into uniformName, excluding the null terminator, is returned in length. If length is NULL, no length is returned. The maximum number of characters that may be written into uniformName, including the null terminator, is specified by bufSize. The returned uniform name can be the name of built-in uniform state as well. The complete list of built-in uniform state is described in section 7.5 of the OpenGL Shading Language Specification. The length of the longest uniform name in program is given by the value of ACTIVE_UNIFORM_MAX_LENGTH, which can be queried with GetProgramiv.

If GetActiveUniformName is not successful, nothing is written to length or uniformName.

Each uniform variable, declared in a shader, is broken down into one or more strings using the ".", " (dot) and "[]" operators, if necessary, to the point that it is legal to pass each string back into GetUniformLocation, for default uniform block uniform names, or GetUniformIndices, for named uniform block uniform names.
2.14. VERTEX SHADERS

Information about active uniforms can be obtained by calling either

```c
void GetActiveUniform( uint program, uint index,
sizei bufSize, sizei *length, int *size, enum *type,
char *name );
```

or

```c
void GetActiveUniformsiv( uint program,
sizei uniformCount, const uint *uniformIndices,
enum pname, int *params );
```

`program` is the name of a program object for which the command `LinkProgram` has been issued in the past. It is not necessary for `program` to have been linked successfully. The link could have failed because the number of active uniforms exceeded the limit.

These commands provide information about the uniform or uniforms selected by `index` or `uniformIndices`, respectively. In `GetActiveUniform`, an `index` of 0 selects the first active uniform, and an `index` of the value of `ACTIVE_UNIFORMS - 1` selects the last active uniform. In `GetActiveUniformsiv`, `uniformIndices` is an array of such active uniform indices. If any index is greater than or equal to the value of `ACTIVE_UNIFORMS`, the error `INVALID_VALUE` is generated.

For the selected uniform, `GetActiveUniform` returns the uniform name as a null-terminated string in `name`. The actual number of characters written into `name`, excluding the null terminator, is returned in `length`. If `length` is `NULL`, no length is returned. The maximum number of characters that may be written into `name`, including the null terminator, is specified by `bufSize`. The returned uniform name can be the name of built-in uniform state as well. The complete list of built-in uniform state is described in section 7.5 of the OpenGL Shading Language Specification. The length of the longest uniform name in `program` is given by `ACTIVE_UNIFORM_MAX_LENGTH`.

Each uniform variable, declared in a shader, is broken down into one or more strings using the "." (dot) and " [ ] " operators, if necessary, to the point that it is legal to pass each string back into `GetUniformLocation`, for default uniform block uniform names, or `GetUniformIndices`, for named uniform block uniform names.

For the selected uniform, `GetActiveUniform` returns the type of the uniform into `type` and the size of the uniform is into `size`. The value in `size` is in units of the uniform type, which can be any of the type name tokens in table 2.13, corresponding to OpenGL Shading Language type keywords also shown in that table.

If one or more elements of an array are active, `GetActiveUniform` will return the name of the array in `name`, subject to the restrictions listed above. The type of
the array is returned in \textit{type}. The \textit{size} parameter contains the highest array element index used, plus one. The compiler or linker determines the highest index used. There will be only one active uniform reported by the GL per uniform array.

\textbf{GetActiveUniform} will return as much information about active uniforms as possible. If no information is available, \textit{length} will be set to zero and \textit{name} will be an empty string. This situation could arise if \textbf{GetActiveUniform} is issued after a failed link.

If an error occurs, nothing is written to \textit{length}, \textit{size}, \textit{type}, or \textit{name}.

Table 2.13: OpenGL Shading Language type tokens returned by `GetActiveUniform` and `GetActiveUniformsiv`, and corresponding shading language keywords declaring each such type.

For `GetActiveUniformsiv`, `uniformCount` indicates both the number of elements in the array of indices `uniformIndices` and the number of parameters written to `params` upon successful return. `pname` identifies a property of each uniform in `uniformIndices` that should be written into the corresponding element of `params`. If an error occurs, nothing will be written to `params`.

If `pname` is `UNIFORM_TYPE`, then an array identifying the types of the uniforms specified by the corresponding array of `uniformIndices` is returned. The returned types can be any of the values in table 2.13.

If `pname` is `UNIFORM_SIZE`, then an array identifying the size of the uniforms specified by the corresponding array of `uniformIndices` is returned. The sizes returned are in units of the type returned by a query of `UNIFORM_TYPE`. For active uniforms that are arrays, the size is the number of active elements in the array; for all other uniforms, the size is one.

If `pname` is `UNIFORM_NAME_LENGTH`, then an array identifying the length, including the terminating null character, of the uniform name strings specified by the corresponding array of `uniformIndices` is returned.

If `pname` is `UNIFORM_BLOCK_INDEX`, then an array identifying the uniform block index of each of the uniforms specified by the corresponding array of `uniformIndices` is returned. The index of a uniform associated with the default uniform block is -1.
If *pname* is `UNIFORM_OFFSET`, then an array of uniform buffer offsets is returned. For uniforms in a named uniform block, the returned value will be its offset, in basic machine units, relative to the beginning of the uniform block in the buffer object data store. For uniforms in the default uniform block, -1 will be returned.

If *pname* is `UNIFORM_ARRAY_STRIDE`, then an array identifying the stride between elements, in basic machine units, of each of the uniforms specified by the corresponding array of `uniformIndices` is returned. The stride of a uniform associated with the default uniform block is -1. Note that this information only makes sense for uniforms that are arrays. For uniforms that are not arrays, but are declared in a named uniform block, an array stride of zero is returned.

If *pname* is `UNIFORM_MATRIX_STRIDE`, then an array identifying the stride between columns of a column-major matrix or rows of a row-major matrix, in basic machine units, of each of the uniforms specified by the corresponding array of `uniformIndices` is returned. The matrix stride of a uniform associated with the default uniform block is -1. Note that this information only makes sense for uniforms that are matrices. For uniforms that are not matrices, but are declared in a named uniform block, a matrix stride of zero is returned.

If *pname* is `UNIFORM_IS_ROW_MAJOR`, then an array identifying whether each of the uniforms specified by the corresponding array of `uniformIndices` is a row-major matrix or not is returned. A value of one indicates a row-major matrix, and a value of zero indicates a column-major matrix, a matrix in the default uniform block, or a non-matrix.

### Loading Uniform Variables In The Default Uniform Block

To load values into the uniform variables of the default uniform block of the program object that is currently in use, use the commands

```c
void Uniform{1234}{if}( int location, T value );
void Uniform{1234}{if}v( int location, sizei count, T value );
void Uniform{1,2,3,4}ui( int location, T value );
void Uniform{1,2,3,4}uiv( int location, sizei count, T value );
void UniformMatrix{234}fv( int location, sizei count, boolean transpose, const float *value );
void UniformMatrix{2x3,3x2,2x4,4x2,3x4,4x3}fv( int location, sizei count, boolean transpose, const float *value );
```
2.14. VERTEX SHADERS

The given values are loaded into the default uniform block uniform variable location identified by `location`.

The `Uniform*f{v}` commands will load `count` sets of one to four floating-point values into a uniform location defined as a float, a floating-point vector, an array of floats, or an array of floating-point vectors.

The `Uniform*i{v}` commands will load `count` sets of one to four integer values into a uniform location defined as a sampler, an integer, an integer vector, an array of samplers, an array of integers, or an array of integer vectors. Only the `Uniform1i{v}` commands can be used to load sampler values (see below).

The `Uniform*ui{v}` commands will load `count` sets of one to four unsigned integer values into a uniform location defined as an unsigned integer, an unsigned integer vector, an array of unsigned integers or an array of unsigned integer vectors.

The `UniformMatrix{234}fv` commands will load `count` $2 \times 2$, $3 \times 3$, or $4 \times 4$ matrices (corresponding to $2$, $3$, or $4$ in the command name) of floating-point values into a uniform location defined as a matrix or an array of matrices. If `transpose` is `FALSE`, the matrix is specified in column major order, otherwise in row major order.

The `UniformMatrix{2x3,3x2,2x4,3x4,4x2,3x4,4x3}fv` commands will load `count` $2 \times 3$, $3 \times 2$, $2 \times 4$, $4 \times 2$, $3 \times 4$, or $4 \times 3$ matrices (corresponding to the numbers in the command name) of floating-point values into a uniform location defined as a matrix or an array of matrices. The first number in the command name is the number of columns; the second is the number of rows. For example, `UniformMatrix2x4fv` is used to load a matrix consisting of two columns and four rows. If `transpose` is `FALSE`, the matrix is specified in column major order, otherwise in row major order.

When loading values for a uniform declared as a boolean, a boolean vector, an array of booleans, or an array of boolean vectors, the `Uniform*{if ui}` set of commands can be used to load boolean values. Type conversion is done by the GL. The uniform is set to `FALSE` if the input value is 0 or 0.0f, and set to `TRUE` otherwise. The `Uniform*` command used must match the size of the uniform, as declared in the shader. For example, to load a uniform declared as a `bvec2`, any of the `Uniform2{if ui}` commands may be used. An `INVALID_OPERATION` error will be generated if an attempt is made to use a non-matching `Uniform*` command. In this example using `Uniform1iv` would generate an error.

For all other uniform types the `Uniform*` command used must match the size and type of the uniform, as declared in the shader. No type conversions are done. For example, to load a uniform declared as a `vec4`, `Uniform4f{v}` must be used. To load a $3 \times 3$ matrix, `UniformMatrix3fv` must be used. An `INVALID_OPERATION` error will be generated if an attempt is made to use a non-matching
Uniform* command. In this example, using Uniform4i\{v\} would generate an error.

When loading \(N\) elements starting at an arbitrary position \(k\) in a uniform declared as an array, elements \(k\) through \(k + N - 1\) in the array will be replaced with the new values. Values for any array element that exceeds the highest array element index used, as reported by GetActiveUniform, will be ignored by the GL.

If the value of location is -1, the Uniform* commands will silently ignore the data passed in, and the current uniform values will not be changed.

If any of the following conditions occur, an INVALID_OPERATION error is generated by the Uniform* commands, and no uniform values are changed:

- if the size indicated in the name of the Uniform* command used does not match the size of the uniform declared in the shader,
- if the uniform declared in the shader is not of type boolean and the type indicated in the name of the Uniform* command used does not match the type of the uniform,
- if \(count\) is greater than one, and the uniform declared in the shader is not an array variable,
- if no variable with a location of location exists in the program object currently in use and location is not -1, or
- if there is no program object currently in use.

### Uniform Blocks

The values of uniforms arranged in named uniform blocks are extracted from buffer object storage. The mechanisms for placing individual uniforms in a buffer object and connecting a uniform block to an individual buffer object are described below.

There is a set of implementation-dependent maximums for the number of active uniform blocks used by each shader (vertex, geometry, and fragment). If the number of uniform blocks used by any shader in the program exceeds its corresponding limit, the program will fail to link. The limits for vertex, geometry, and fragment shaders can be obtained by calling GetIntegerv with pname values of MAX_VERTEX_UNIFORM_BLOCKS, MAX_GEOMETRY_UNIFORM_BLOCKS, and MAX_FRAGMENT_UNIFORM_BLOCKS, respectively.

Additionally, there is an implementation-dependent limit on the sum of the number of active uniform blocks used by each shader of a program. If a uniform block is used by multiple shaders, each such use counts separately against this
combined limit. The combined uniform block use limit can be obtained by calling `GetIntegerv` with a `pname` of `MAX_COMBINED_UNIFORM_BLOCKS`.

When a named uniform block is declared by multiple shaders in a program, it must be declared identically in each shader. The uniforms within the block must be declared with the same names and types, and in the same order. If a program contains multiple shaders with different declarations for the same named uniform block differs between shader, the program will fail to link.

**Uniform Buffer Object Storage**

When stored in buffer objects associated with uniform blocks, uniforms are represented in memory as follows:

- Members of type `bool` are extracted from a buffer object by reading a single uint-typed value at the specified offset. All non-zero values correspond to true, and zero corresponds to false.

- Members of type `int` are extracted from a buffer object by reading a single int-typed value at the specified offset.

- Members of type `uint` are extracted from a buffer object by reading a single uint-typed value at the specified offset.

- Members of type `float` are extracted from a buffer object by reading a single float-typed value at the specified offset.

- Vectors with $N$ elements with basic data types of `bool`, `int`, `uint`, or `float` are extracted as $N$ values in consecutive memory locations beginning at the specified offset, with components stored in order with the first (X) component at the lowest offset. The GL data type used for component extraction is derived according to the rules for scalar members above.

- Column-major matrices with $C$ columns and $R$ rows (using the type `matCxR`, or simply `matC` if $C = R$) are treated as an array of $C$ floating-point column vectors, each consisting of $R$ components. The column vectors will be stored in order, with column zero at the lowest offset. The difference in offsets between consecutive columns of the matrix will be referred to as the column stride, and is constant across the matrix. The column stride, `UNIFORM_MATRIX_STRIDE`, is an implementation-dependent value and may be queried after a program is linked.

- Row-major matrices with $C$ columns and $R$ rows (using the type `matCxC`, or simply `matC` if $C = R$) are treated as an array of $R$ floating-point row
vectors, each consisting of $C$ components. The row vectors will be stored in order, with row zero at the lowest offset. The difference in offsets between consecutive rows of the matrix will be referred to as the row stride, and is constant across the matrix. The row stride, UNIFORM_MATRIX_STRIDE, is an implementation-dependent value and may be queried after a program is linked.

- Arrays of scalars, vectors, and matrices are stored in memory by element order, with array member zero at the lowest offset. The difference in offsets between each pair of elements in the array in basic machine units is referred to as the array stride, and is constant across the entire array. The array stride, UNIFORM_ARRAY_STRIDE, is an implementation-dependent value and may be queried after a program is linked.

**Standard Uniform Block Layout**

By default, uniforms contained within a uniform block are extracted from buffer storage in an implementation-dependent manner. Applications may query the offsets assigned to uniforms inside uniform blocks with query functions provided by the GL.

The layout qualifier provides shaders with control of the layout of uniforms within a uniform block. When the std140 layout is specified, the offset of each uniform in a uniform block can be derived from the definition of the uniform block by applying the set of rules described below.

If a uniform block is declared in multiple shaders linked together into a single program, the link will fail unless the uniform block declaration, including layout qualifier, are identical in all such shaders.

When using the std140 storage layout, structures will be laid out in buffer storage with its members stored in monotonically increasing order based on their location in the declaration. A structure and each structure member have a base offset and a base alignment, from which an aligned offset is computed by rounding the base offset up to a multiple of the base alignment. The base offset of the first member of a structure is taken from the aligned offset of the structure itself. The base offset of all other structure members is derived by taking the offset of the last basic machine unit consumed by the previous member and adding one. Each structure member is stored in memory at its aligned offset. The members of a top-level uniform block are laid out in buffer storage by treating the uniform block as a structure with a base offset of zero.

1. If the member is a scalar consuming $N$ basic machine units, the base alignment is $N$.  

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
2.14. **VERTEX SHADERS**

2. If the member is a two- or four-component vector with components consuming \( N \) basic machine units, the base alignment is \( 2N \) or \( 4N \), respectively.

3. If the member is a three-component vector with components consuming \( N \) basic machine units, the base alignment is \( 4N \).

4. If the member is an array of scalars or vectors, the base alignment and array stride are set to match the base alignment of a single array element, according to rules (1), (2), and (3), and rounded up to the base alignment of a vec4. The array may have padding at the end; the base offset of the member following the array is rounded up to the next multiple of the base alignment.

5. If the member is a column-major matrix with \( C \) columns and \( R \) rows, the matrix is stored identically to an array of \( C \) column vectors with \( R \) components each, according to rule (4).

6. If the member is an array of \( S \) column-major matrices with \( C \) columns and \( R \) rows, the matrix is stored identically to a row of \( S \times C \) column vectors with \( R \) components each, according to rule (4).

7. If the member is a row-major matrix with \( C \) columns and \( R \) rows, the matrix is stored identically to an array of \( R \) row vectors with \( C \) components each, according to rule (4).

8. If the member is an array of \( S \) row-major matrices with \( C \) columns and \( R \) rows, the matrix is stored identically to a row of \( S \times R \) row vectors with \( C \) components each, according to rule (4).

9. If the member is a structure, the base alignment of the structure is \( N \), where \( N \) is the largest base alignment value of any of its members, and rounded up to the base alignment of a vec4. The individual members of this substructure are then assigned offsets by applying this set of rules recursively, where the base offset of the first member of the sub-structure is equal to the aligned offset of the structure. The structure may have padding at the end; the base offset of the member following the sub-structure is rounded up to the next multiple of the base alignment of the structure.

10. If the member is an array of \( S \) structures, the \( S \) elements of the array are laid out in order, according to rule (9).
2.14. VERTEX SHADERS

Uniform Buffer Object Bindings

The value an active uniform inside a named uniform block is extracted from the data store of a buffer object bound to one of an array of uniform buffer binding points. The number of binding points can be queried using `GetIntegerv` with the constant `MAX_UNIFORM_BUFFER_BINDINGS`.

Regions of buffer objects are bound as storage for uniform blocks by calling one of the commands `BindBufferRange` or `BindBufferBase` (see section 2.9.1) with `target` set to `UNIFORM_BUFFER`. In addition to the general errors described in section 2.9.1, `BindBufferRange` will generate an `INVALID_VALUE` error if `index` is greater than or equal to the value of `MAX_UNIFORM_BUFFER_BINDINGS`, or if `offset` is not a multiple of the implementation-dependent alignment requirement (the value of `UNIFORM_BUFFER_OFFSET_ALIGNMENT`).

Each of a program’s active uniform blocks has a corresponding uniform buffer object binding point. This binding point can be assigned by calling:

```c
void UniformBlockBinding( uint program, 
                         uint uniformBlockIndex, uint uniformBlockBinding );
```

`program` is a name of a program object for which the command `LinkProgram` has been issued in the past.

An `INVALID_VALUE` error is generated if `uniformBlockIndex` is not an active uniform block index of `program`, or if `uniformBlockBinding` is greater than or equal to the value of `MAX_UNIFORM_BUFFER_BINDINGS`.

If successful, `UniformBlockBinding` specifies that `program` will use the data store of the buffer object bound to the binding point `uniformBlockBinding` to extract the values of the uniforms in the uniform block identified by `uniformBlockIndex`.

When executing shaders that access uniform blocks, the binding point corresponding to each active uniform block must be populated with a buffer object with a size no smaller than the minimum required size of the uniform block (the value of `UNIFORM_BLOCK_DATA_SIZE`). For binding points populated by `BindBufferRange`, the size in question is the value of the `size` parameter. If any active uniform block is not backed by a sufficiently large buffer object, the results of shader execution are undefined, and may result in GL interruption or termination. Shaders may be executed to process the primitives and vertices specified between `Begin` and `End`, or by vertex array commands (see section 2.8). Shaders may also be executed as a result of `DrawPixels`, `Bitmap`, or `RasterPos*` commands.

When a program object is linked or re-linked, the uniform buffer object binding point assigned to each of its active uniform blocks is reset to zero.
2.14.5 Samplers

Samplers are special uniforms used in the OpenGL Shading Language to identify the texture object used for each texture lookup. The value of a sampler indicates the texture image unit being accessed. Setting a sampler’s value to \( i \) selects texture image unit number \( i \). The values of \( i \) range from zero to the implementation-dependent maximum supported number of texture image units.

The type of the sampler identifies the target on the texture image unit. The texture object bound to that texture image unit’s target is then used for the texture lookup. For example, a variable of type \texttt{sampler2D} selects target \texttt{TEXTURE_2D} on its texture image unit. Binding of texture objects to targets is done as usual with \texttt{BindTexture}. Selecting the texture image unit to bind to is done as usual with \texttt{ActiveTexture}.

The location of a sampler needs to be queried with \texttt{GetUniformLocation}, just like any uniform variable. Sampler values need to be set by calling \texttt{Uniform1i(v)}. Loading samplers with any of the other \texttt{Uniform*} entry points is not allowed and will result in an \texttt{INVALID_OPERATION} error.

It is not allowed to have variables of different sampler types pointing to the same texture image unit within a program object. This situation can only be detected at the next rendering command issued, and an \texttt{INVALID_OPERATION} error will then be generated.

Active samplers are samplers actually being used in a program object. The \texttt{LinkProgram} command determines if a sampler is active or not. The \texttt{LinkProgram} command will attempt to determine if the active samplers in the shader(s) contained in the program object exceed the maximum allowable limits. If it determines that the count of active samplers exceeds the allowable limits, then the link fails (these limits can be different for different types of shaders). Each active sampler variable counts against the limit, even if multiple samplers refer to the same texture image unit. If this cannot be determined at link time, for example if the program object only contains a vertex shader, then it will be determined at the next rendering command issued, and an \texttt{INVALID_OPERATION} error will then be generated.

2.14.6 Varying Variables

A vertex shader may define one or more \textit{varying} variables (see the OpenGL Shading Language Specification). Varying variables are outputs of a vertex shader. The OpenGL Shading Language Specification also defines a set of built-in varying and special variables that vertex shaders can write to (see sections 7.1 and 7.6 of the OpenGL Shading Language Specification). These varying variables are either used
as the mechanism to communicate values to a geometry shader, if one is active, or to communicate values to the fragment shader and to the fixed-function processing that occurs after vertex shading.

If a geometry shader is not active, the values of all varying and special variables are expected to be interpolated across the primitive being rendered, unless flatshaded. Otherwise the values of all varying and special variables are collected by the primitive assembly stage and passed on to the geometry shader once enough data for one primitive has been collected (see section 2.15).

The number of components (individual scalar numeric values) of varying and special variables that can be written by the vertex shader, whether or not a geometry shader is active, is given by the value of the implementation-dependent constant MAX_VERTEX_OUTPUT_COMPONENTS. Outputs declared as vectors, matrices, and arrays will all consume multiple components.

When a program is linked, all components of any varying and special variable written by a vertex shader will count against this limit. A program whose vertex shader writes more than the value of MAX_VERTEX_OUTPUT_COMPONENTS components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Additionally, when linking a program containing only a vertex and fragment shader, there is a limit on the total number of components used as vertex shader outputs or fragment shader inputs. This limit is given by the value of the implementation-dependent constant MAX_VARYING_COMPONENTS. Each varying or special variable component used as either a vertex shader output or fragment shader input count against this limit, except for the components of gl_Position. A program containing only a vertex and fragment shader that accesses more than this limit’s worth of components of varying and special variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Each program object can specify a set of one or more vertex or geometry shader output variables to be recorded in transform feedback mode (see section 2.19). When a geometry shader is active (see section 2.15), transform feedback records the values of the selected geometry shader output variables from the emitted vertices. Otherwise, the values of the selected vertex shader output variables are recorded. The values to record are specified with the command

```c
void TransformFeedbackVaryings( uint program,
    sizei count, const char **varyings, enum bufferMode );
```

`program` specifies the program object. `count` specifies the number of varying variables used for transform feedback. `varyings` is an array of `count` zero-
terminated strings specifying the names of the varying variables to use for transform feedback. The varying variables specified in `varyings` can be either built-in varying variables (beginning with "gl_") or user-defined ones. Varying variables are written out in the order they appear in the array `varyings`. `bufferMode` is either `INTERLEAVED_ATTRIBS` or `SEPARATE_ATTRIBS`, and identifies the mode used to capture the varying variables when transform feedback is active. The error `INVALID_VALUE` is generated if `bufferMode` is `SEPARATE_ATTRIBS` and `count` is greater than the value of the implementation-dependent limit `MAX_TRANSFORM_FEEDBACK_SEPARATE_ATTRIBS`.

The state set by `TransformFeedbackVaryings` has no effect on the execution of the program until `program` is subsequently linked. When `LinkProgram` is called, the program is linked so that the values of the specified varying variables for the vertices of each primitive generated by the GL are written to a single buffer object (if the buffer mode is `INTERLEAVED_ATTRIBS`) or multiple buffer objects (if the buffer mode is `SEPARATE_ATTRIBS`). A program will fail to link if:

- the `count` specified by `TransformFeedbackVaryings` is non-zero, but the program object has no vertex or geometry shader;
- any variable name specified in the `varyings` array is not declared as an output in the vertex shader (or the geometry shader, if active);
- any two entries in the `varyings` array specify the same varying variable;
- the total number of components to capture in any varying variable in `varyings` is greater than the constant `MAX_TRANSFORM_FEEDBACK_SEPARATE_COMPONENTS` and the buffer mode is `SEPARATE_ATTRIBS`; or
- the total number of components to capture is greater than the constant `MAX_TRANSFORM_FEEDBACK_INTERLEAVED_COMPONENTS` and the buffer mode is `INTERLEAVED_ATTRIBS`.

To determine the set of varying variables in a linked program object that will be captured in transform feedback mode, the command:

```c
void GetTransformFeedbackVarying ( uint program,
    uint index, sizei bufSize, sizei *length, sizei *size,
    enum *type, char *name );
```

provides information about the varying variable selected by `index`. An `index` of 0 selects the first varying variable specified in the `varyings` array of `TransformFeedbackVaryings`, and an `index` of `TRANSFORM_FEEDBACK_VARYINGS-1` selects the
last such varying variable. The value of \texttt{TRANSFORM\_FEEDBACK\_VARYINGS} can be queried with \texttt{GetProgramiv} (see section 6.1.16). If \texttt{index} is greater than or equal to \texttt{TRANSFORM\_FEEDBACK\_VARYINGS}, the error \texttt{INVALID\_VALUE} is generated. The parameter \texttt{program} is the name of a program object for which the command \texttt{LinkProgram} has been issued in the past. If \texttt{program} has not been linked, the error \texttt{INVALID\_OPERATION} is generated. If a new set of varying variables is specified by \texttt{TransformFeedbackVaryings} after a program object has been linked, the information returned by \texttt{GetTransformFeedbackVarying} will not reflect those variables until the program is re-linked.

The name of the selected varying is returned as a null-terminated string in \texttt{name}. The actual number of characters written into \texttt{name}, excluding the null terminator, is returned in \texttt{length}. If \texttt{length} is \texttt{NULL}, no length is returned. The maximum number of characters that may be written into \texttt{name}, including the null terminator, is specified by \texttt{bufSize}. The returned varying name can be the name of a user defined varying variable or the name of a built-in varying (which begin with the prefix \texttt{gl_}, see the OpenGL Shading Language Specification for a complete list).

The length of the longest varying name in \texttt{program} is given by \texttt{TRANSFORM\_FEEDBACK\_VARYING\_MAX\_LENGTH}, which can be queried with \texttt{GetProgramiv} (see section 6.1.16).

For the selected varying variable, its type is returned into \texttt{type}. The size of the varying is returned into \texttt{size}. The value in \texttt{size} is in units of the type returned in \texttt{type}. The type returned can be any of the scalar, vector, or matrix attribute types returned by \texttt{GetActiveAttrib}. If an error occurred, the return parameters \texttt{length}, \texttt{size}, \texttt{type} and \texttt{name} will be unmodified. This command will return as much information about the varying variables as possible. If no information is available, \texttt{length} will be set to zero and \texttt{name} will be an empty string. This situation could arise if \texttt{GetTransformFeedbackVarying} is called after a failed link.

\section{Shader Execution}

If a successfully linked program object that contains a vertex shader is made current by calling \texttt{UseProgram}, the executable version of the vertex shader is used to process incoming vertex values, rather than the fixed-function vertex processing described in sections 2.12 through 2.13. In particular,

\begin{itemize}
  \item The model-view and projection matrices are not applied to vertex coordinates (section 2.12).
  \item The texture matrices are not applied to texture coordinates (section 2.12.1).
\end{itemize}
2.14. VERTEX SHADERS

- Normals are not transformed to eye coordinates, and are not rescaled or normalized (section 2.12.2).
- Normalization of AUTO_NORMAL evaluated normals is not performed. (section 5.1).
- Texture coordinates are not generated automatically (section 2.12.3).
- Per vertex lighting is not performed (section 2.13.1).
- Color material computations are not performed (section 2.13.3).
- Color index lighting is not performed (section 2.13.5).
- All of the above applies when setting the current raster position (section 2.24).

If a geometry shader (see section 2.15) is active, vertices processed by the vertex shader are passed to the geometry shader for further processing. Otherwise, the following operations are applied to vertices processed by the vertex shader:

- Color clamping or masking (section 2.13.6).
- Perspective division on clip coordinates (section 2.16).
- Viewport mapping, including depth range scaling (section 2.16.1).
- Flatshading (section 2.21).
- Clipping, including client-defined clip planes (section 2.22).
- Front face determination (section 2.13.1).
- Color, texture coordinate, fog, point-size and generic attribute clipping (section 2.22.1).
- Final color processing (section 2.23).

There are several special considerations for vertex shader execution described in the following sections.

**Shader Only Texturing**

This section describes texture functionality that is only accessible through vertex, geometry, or fragment shaders. Also refer to section 3.9 and to section 8.7 of the OpenGL Shading Language Specification,
Texel Fetches

The OpenGL Shading Language texel fetch functions provide the ability to extract a single texel from a specified texture image. The integer coordinates passed to the texel fetch functions are used directly as the texel coordinates \((i, j, k)\) into the texture image. This in turn means the texture image is point-sampled (no filtering is performed).

The level of detail accessed is computed by adding the specified level-of-detail parameter \(lod\) to the base level of the texture, \(level_{\text{base}}\).

The texel fetch functions can not perform depth comparisons or access cube maps. Unlike filtered texel accesses, texel fetches do not support LOD clamping or any texture wrap mode, and require a mipmapped minification filter to access any level of detail other than the base level.

The results of the texel fetch are undefined if any of the following conditions hold:

- the computed level of detail is less than the texture’s base level \((level_{\text{base}})\) or greater than the maximum level \((level_{\text{max}})\)
- the computed level of detail is not the texture’s base level and the texture’s minification filter is \textsc{nearest} or \textsc{linear}
- the layer specified for array textures is negative or greater than the number of layers in the array texture,
- the texel coordinates \((i, j, k)\) refer to a texel outside the defined extents of the specified level of detail, where any of
  \[
  \begin{align*}
  i &< -b_s \\
  j &< -b_s \\
  k &< -b_s \\
  i &\geq w_s - b_s \\
  j &\geq h_s - b_s \\
  k &\geq d_s - b_s
  \end{align*}
  \]
  and the size parameters \(b_s, w_s, h_s,\) and \(d_s\) refer to the border size, width, height, and depth of the image, as in equation 3.17
- the texture being accessed is not complete, as defined in section 3.9.12.

Multisample Texel Fetches

Multisample buffers do not have mipmaps, and there is no level of detail parameter for multisample texel fetches. Instead, an integer parameter selects the sample number to be fetched from the buffer. The number identifying the sample is the
same as the value used to query the sample location using \texttt{GetMultisamplefv}.
Multisample textures support only \texttt{NEAREST} filtering.

Additionally, this fetch may only be performed on a multisample texture sampler. No other sample or fetch commands may be performed on a multisample texture sampler.

**Texture Size Query**

The OpenGL Shading Language texture size functions provide the ability to query the size of a texture image. The LOD value \texttt{lod} passed in as an argument to the texture size functions is added to the \texttt{levelbase} of the texture to determine a texture image level. The dimensions of that image level, excluding a possible border, are then returned. If the computed texture image level is outside the range \([\texttt{levelbase}, \texttt{levelmax}]\), the results are undefined. When querying the size of an array texture, both the dimensions and the layer index are returned.

**Texture Access**

Shaders have the ability to do a lookup into a texture map. The maximum number of texture image units available to vertex, geometry, or fragment shaders are respectively the values of the implementation-dependent constants \texttt{MAX_VERTEX_TEXTURE_IMAGE_UNITS}, \texttt{MAX_GEOMETRY_TEXTURE_IMAGE_UNITS}, and \texttt{MAX_TEXTURE_IMAGE_UNITS}. The vertex shader, geometry shader, and fragment processing combined cannot use more than the value of \texttt{MAX_COMBINED_TEXTURE_IMAGE_UNITS} texture image units. If more than one of the vertex shader, geometry shader, and fragment processing stage access the same texture image unit, each such access counts separately against the \texttt{MAX_COMBINED_TEXTURE_IMAGE_UNITS} limit.

When a texture lookup is performed in a vertex or geometry shader, the filtered texture value \(\tau\) is computed in the manner described in sections 3.9.9 and 3.9.10, and converted to a texture source color \(C_s\) according to table 3.25 (section 3.9.15).

A four-component vector \((R_s, G_s, B_s, A_s)\) is returned to the shader. Texture lookup functions (see section 8.7 of the OpenGL Shading Language Specification) may return floating-point, signed, or unsigned integer values depending on the function and the internal format of the texture.

In a vertex or geometry shader, it is not possible to perform automatic level-of-detail calculations using partial derivatives of the texture coordinates with respect to window coordinates as described in section 3.9.9. Hence, there is no automatic selection of an image array level. Minification or magnification of a texture map is controlled by a level-of-detail value optionally passed as an argument in the
texture lookup functions. If the texture lookup function supplies an explicit level-of-detail value \( l \), then the pre-bias level-of-detail value \( \lambda_{\text{base}}(x, y) = l \) (replacing equation 3.18). If the texture lookup function does not supply an explicit level-of-detail value, then \( \lambda_{\text{base}}(x, y) = 0 \). The scale factor \( \rho(x, y) \) and its approximation function \( f(x, y) \) (see equation 3.22) are ignored.

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with a reference depth value specified in the coordinates passed to the texture lookup function, as described in section 3.9.16. The comparison operation is requested in the shader by using any of the shadow sampler types \( \text{sampler1DShadow} \), \( \text{sampler2DShadow} \), or \( \text{sampler2DRectShadow} \), and in the texture using the \text{TEXTURE_COMPARE_-MODE} parameter. These requests must be consistent; the results of a texture lookup are undefined if any of the following conditions are true:

- The sampler used in a texture lookup function is not one of the shadow sampler types, the texture object’s internal format is \text{DEPTH_COMPONENT} or \text{DEPTH_STENCIL}, and the \text{TEXTURE_COMPARE_MODE} is not \text{NONE}.

- The sampler used in a texture lookup function is one of the shadow sampler types, the texture object’s internal format is \text{DEPTH_COMPONENT} or \text{DEPTH_STENCIL}, and the \text{TEXTURE_COMPARE_MODE} is \text{NONE}.

- The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object’s internal format is not \text{DEPTH_COMPONENT} or \text{DEPTH_STENCIL}.

The stencil index texture internal component is ignored if the base internal format is \text{DEPTH_STENCIL}.

Using a sampler in a vertex or geometry shader will return \((R, G, B, A) = (0, 0, 0, 1)\) if the sampler’s associated texture is not complete, as defined in section 3.9.12.

**Shader Inputs**

Besides having access to vertex attributes and uniform variables, vertex shaders can access the read-only built-in variables \( \text{gl_VertexID} \) and \( \text{gl_InstanceID} \).

\( \text{gl_VertexID} \) holds the integer index \( i \) explicitly passed to \text{ArrayElement} to specify the vertex, or implicitly passed by \text{DrawArrays} or one of the other drawing commands defined in section 2.8.1. The value of \( \text{gl_VertexID} \) is defined if and only if:
2.14. VERTEX SHADERS

- the vertex comes from a vertex array command that specifies a complete primitive (a vertex array drawing command other than \texttt{ArrayElement}).
- all enabled vertex arrays have non-zero buffer object bindings, and
- the vertex does not come from a display list, even if the display list was compiled using one of the vertex array commands described above with data sourced from buffer objects.

\texttt{gl\_InstanceId} holds the integer index of the current primitive in an instanced draw call (see section 2.8.1).

Section 7.1 of the OpenGL Shading Language Specification also describes these variables.

\textbf{Shader Outputs}

A vertex shader can write to built-in as well as user-defined varying variables. These values are expected to be interpolated across the primitive it outputs, unless they are specified to be flat shaded. Refer to section 2.21 and sections 4.3.6, 7.1, and 7.6 of the OpenGL Shading Language Specification for more detail.

The built-in output variables \texttt{gl\_FrontColor}, \texttt{gl\_BackColor}, \texttt{gl\_FrontSecondaryColor}, and \texttt{gl\_BackSecondaryColor} hold the front and back colors for the primary and secondary colors for the current vertex.

The built-in output variable \texttt{gl\_TexCoord[]} is an array and holds the set of texture coordinates for the current vertex.

The built-in output variable \texttt{gl\_FogFragCoord} is used as the \texttt{c} value described in section 3.11.

The built-in special variable \texttt{gl\_Position} is intended to hold the homogeneous vertex position. Writing \texttt{gl\_Position} is optional.

The built-in special variables \texttt{gl\_ClipVertex} and \texttt{gl\_ClipDistance} respectively hold the vertex coordinate and clip distance(s) used in the clipping stage, as described in section 2.22. If clipping is enabled, only one of \texttt{gl\_ClipVertex} and \texttt{gl\_ClipDistance} should be written.

The built-in special variable \texttt{gl\_PointSize}, if written, holds the size of the point to be rasterized, measured in pixels.

\textbf{Position Invariance}

If a vertex shader uses the built-in function \texttt{ftransform} to generate a vertex position, then this generally guarantees that the transformed position will be the same
whether using this vertex shader or the fixed-function pipeline. This allows for cor-
rect multi-pass rendering algorithms, where some passes use fixed-function vertex 
transformation and other passes use a vertex shader. If a vertex shader does not use 
\texttt{ftransform} to generate a position, transformed positions are not guaranteed to 
match, even if the sequence of instructions used to compute the position match the 
sequence of transformations described in section \ref{2.12}.

\section*{Validation}

It is not always possible to determine at link time if a program object actually will 
execute. Therefore validation is done when the first rendering command is issued, 
to determine if the currently active program object can be executed. If it cannot be 
executed then no fragments will be rendered, and the error \texttt{INVALID_OPERATION} 
will be generated.

This error is generated by \texttt{Begin}, \texttt{RasterPos}, or any command that performs 
an implicit \texttt{Begin} if:

- any two active samplers in the current program object are of different types, 
  but refer to the same texture image unit,

- any active sampler in the current program object refers to a texture image 
  unit where fixed-function fragment processing accesses a texture target that 
  does not match the sampler type, or

- the sum of the number of active samplers in the program and the number of 
  texture image units enabled for fixed-function fragment processing exceeds 
  the combined limit on the total number of texture image units allowed.

Fixed-function fragment processing operations will be performed if the pro-
gram object in use has no fragment shader.

The \texttt{INVALID_OPERATION} error reported by these rendering commands may 
not provide enough information to find out why the currently active program object 
would not execute. No information at all is available about a program object that 
would still execute, but is inefficient or suboptimal given the current GL state. As 
a development aid, use the command

\begin{verbatim}
void ValidateProgram( uint program );
\end{verbatim}

to validate the program object \texttt{program} against the current GL state. Each program 
object has a boolean status, \texttt{VALIDATE_STATUS}, that is modified as a result of 
validation. This status can be queried with \texttt{GetProgramiv} (see section \ref{6.1.16}).
If validation succeeded this status will be set to TRUE, otherwise it will be set to FALSE. If validation succeeded the program object is guaranteed to execute, given the current GL state. If validation failed, the program object is guaranteed to not execute, given the current GL state.

ValidateProgram will check for all the conditions that could lead to an INVALID_OPERATION error when rendering commands are issued, and may check for other conditions as well. For example, it could give a hint on how to optimize some piece of shader code. The information log of program is overwritten with information on the results of the validation, which could be an empty string. The results written to the information log are typically only useful during application development; an application should not expect different GL implementations to produce identical information.

A shader should not fail to compile, and a program object should not fail to link due to lack of instruction space or lack of temporary variables. Implementations should ensure that all valid shaders and program objects may be successfully compiled, linked and executed.

Undefined Behavior

When using array or matrix variables in a shader, it is possible to access a variable with an index computed at run time that is outside the declared extent of the variable. Such out-of-bounds reads will return undefined values; out-of-bounds writes will have undefined results and could corrupt other variables used by shader or the GL. The level of protection provided against such errors in the shader is implementation-dependent.

2.14.8 Required State

The GL maintains state to indicate which shader and program object names are in use. Initially, no shader or program objects exist, and no names are in use.

The state required per shader object consists of:

- An unsigned integer specifying the shader object name.
- An integer holding the value of SHADER_TYPE.
- A boolean holding the delete status, initially FALSE.
- A boolean holding the status of the last compile, initially FALSE.
- An array of type char containing the information log, initially empty.
2.14. VERTEX SHADERS

- An integer holding the length of the information log.
- An array of type char containing the concatenated shader string, initially empty.
- An integer holding the length of the concatenated shader string.

The state required per program object consists of:

- An unsigned integer indicating the program object name.
- A boolean holding the delete status, initially FALSE.
- A boolean holding the status of the last link attempt, initially FALSE.
- A boolean holding the status of the last validation attempt, initially FALSE.
- An integer holding the number of attached shader objects.
- A list of unsigned integers to keep track of the names of the shader objects attached.
- An array of type char containing the information log, initially empty.
- An integer holding the length of the information log.
- An integer holding the number of active uniforms.
  For each active uniform, three integers, holding its location, size, and type, and an array of type char holding its name.
- An array holding the values of each active uniform.
- An integer holding the number of active attributes.
  For each active attribute, three integers holding its location, size, and type, and an array of type char holding its name.

Additional state required to support vertex shaders consists of:

- A bit indicating whether or not vertex program two-sided color mode is enabled, initially disabled.
- A bit indicating whether or not program point size mode (section 3.4.1) is enabled, initially disabled.

Additionally, one unsigned integer is required to hold the name of the current program object, if any.
2.15 Geometry Shaders

After vertices are processed, they are arranged into primitives, as described in section 2.6.1. This section describes optional geometry shaders, an additional pipeline stage defining operations to further process those primitives. Geometry shaders are defined by source code in the OpenGL Shading Language, in the same manner as vertex shaders. They operate on a single primitive at a time and emit one or more output primitives, all of the same type, which are then processed like an equivalent OpenGL primitive specified by the application. The original primitive is discarded after geometry shader execution. The inputs available to a geometry shader are the transformed attributes of all the vertices that belong to the primitive. Additional adjacency primitives are available which also make the transformed attributes of neighboring vertices available to the shader. The results of the shader are a new set of transformed vertices, arranged into primitives by the shader.

The geometry shader pipeline stage is inserted after primitive assembly, prior to transform feedback (section 2.19).

A geometry shader only applies when the GL is in RGBA mode. Its operation in color index mode is undefined.

Geometry shaders are created as described in section 2.14.1 using a type of GEOMETRY_SHADER. They are attached to and used in program objects as described in section 2.14.2. When the program object currently in use includes a geometry shader, its geometry shader is considered active, and is used to process primitives. If the program object has no geometry shader, or no program object is in use, this stage is bypassed.

A program object that includes a geometry shader must also include a vertex shader; otherwise a link error will occur.

2.15.1 Geometry Shader Input Primitives

A geometry shader can operate on one of five input primitive types. Depending on the input primitive type, one to six input vertices are available when the shader is executed. Each input primitive type supports a subset of the primitives provided by the GL. If a geometry shader is active, Begin, and any command that performs an implicit Begin, will generate an INVALID_OPERATION error if the primitive mode parameter is incompatible with the input primitive type of the currently active program object, as discussed below.

A geometry shader that accesses more input vertices than are available for a given input primitive type can be successfully compiled, because the input primitive type is not part of the shader object. However, a program object containing a shader object that accesses more input vertices than are available for the input
primitive type of the program object will not link.

The input primitive type is specified in the geometry shader source code using an input layout qualifier, as described in the OpenGL Shading Language Specification. A program will fail to link if the input primitive type is not specified by any geometry shader object attached to the program, or if it is specified differently by multiple geometry shader objects. The input primitive type may be queried by calling `GetProgramiv` with the symbolic constant `GEOMETRY_INPUT_TYPE`. The supported types and the corresponding OpenGL Shading Language input layout qualifier keywords are:

**Points** (points)

Geometry shaders that operate on points are valid only for the `POINTS` primitive type. There is only a single vertex available for each geometry shader invocation.

**Lines** (lines)

Geometry shaders that operate on line segments are valid only for the `_LINES`, `LINE_STRIP`, and `LINE_LOOP` primitive types. There are two vertices available for each geometry shader invocation. The first vertex refers to the vertex at the beginning of the line segment and the second vertex refers to the vertex at the end of the line segment. See also section 2.15.4.

**Lines with Adjacency** (lines_adjaceny)

Geometry shaders that operate on line segments with adjacent vertices are valid only for the `_LINES_ADJACENCY` and `LINE_STRIP_ADJACENCY` primitive types. There are four vertices available for each program invocation. The second vertex refers to attributes of the vertex at the beginning of the line segment and the third vertex refers to the vertex at the end of the line segment. The first and fourth vertices refer to the vertices adjacent to the beginning and end of the line segment, respectively.

**Triangles** (triangles)

Geometry shaders that operate on triangles are valid for the `_TRIANGLES`, `TRIANGLE_STRIP` and `TRIANGLE_FAN` primitive types. There are three vertices available for each program invocation. The first, second and third vertices refer to attributes of the first, second and third vertex of the triangle, respectively.

**Triangles with Adjacency** (triangles_adjacency)

Geometry shaders that operate on triangles with adjacent vertices are valid for the `_TRIANGLES_ADJACENCY` and `TRIANGLE_STRIP_ADJACENCY` primitive
types. There are six vertices available for each program invocation. The first, third and fifth vertices refer to attributes of the first, second and third vertex of the triangle, respectively. The second, fourth and sixth vertices refer to attributes of the vertices adjacent to the edges from the first to the second vertex, from the second to the third vertex, and from the third to the first vertex, respectively.

### 2.15.2 Geometry Shader Output Primitives

A geometry shader can generate primitives of one of three types. The supported output primitive types are points (POINTS), line strips (LINE_STRIP), and triangle strips (TRIANGLE_STRIP). The vertices output by the geometry shader are assembled into points, lines, or triangles based on the output primitive type in the manner described in section 2.6.1. The resulting primitives are then further processed as described in section 2.15.4. If the number of vertices emitted by the geometry shader is not sufficient to produce a single primitive, nothing is drawn. The number of vertices output by the geometry shader is limited to a maximum count specified in the shader.

The output primitive type and maximum output vertex count are specified in the geometry shader source code using an output layout qualifier, as described in section 4.3.8.1 of the OpenGL Shading Language Specification. A program will fail to link if either the output primitive type or maximum output vertex count are not specified by any geometry shader object attached to the program, or if they are specified differently by multiple geometry shader objects. The output primitive type and maximum output vertex count of a linked program may be queried by calling `GetProgramiv` with the symbolic constants `GEOMETRY_OUTPUT_TYPE` and `GEOMETRY_VERTICES_OUT`, respectively.

### 2.15.3 Geometry Shader Variables

Geometry shaders can access uniforms belonging to the current program object. The amount of storage available for geometry shader uniform variables is specified by the implementation dependent constant `MAX_GEOMETRY_UNIFORM_COMPONENTS`. This value represents the number of individual floating-point, integer, or boolean values that can be held in uniform variable storage for a geometry shader. A link error will be generated if an attempt is made to utilize more than the space available for geometry shader uniform variables. Uniforms are manipulated as described in section 2.14.4. Geometry shaders also have access to samplers to perform texturing operations, as described in sections 2.14.5 and 3.9.

Geometry shaders can access the transformed attributes of all vertices for their input primitive type using input varying variables. A vertex shader writing to out-
2.15. **GEOMETRY SHADERS**

Put varying variables generates the values of these input varying variables, including values for built-in as well as user-defined varying variables. Values for any varying variables that are not written by a vertex shader are undefined. Additionally, a geometry shader has access to a built-in variable that holds the ID of the current primitive. This ID is generated by the primitive assembly stage that sits in between the vertex and geometry shader.

Additionally, geometry shaders can write to one or more varying variables for each vertex they output. These values are optionally flatshaded (using the OpenGL Shading Language varying qualifier `flat`) and clipped, then the clipped values interpolated across the primitive (if not flatshaded). The results of these interpolations are available to the fragment shader, if one is active. Geometry shaders can also write to a set of built-in varying variables defined in the OpenGL Shading Language, corresponding to the values required for fixed-function processing that occurs after geometry processing.

### 2.15.4 Geometry Shader Execution Environment

If a successfully linked program object that contains a geometry shader is made current by calling **UseProgram**, the executable version of the geometry shader is used to process primitives resulting from the primitive assembly stage.

The following operations are applied to the primitives that are the result of executing a geometry shader:

- Color clamping or masking (section 2.13.6).
- Perspective division on clip coordinates (section 2.16).
- Viewport mapping, including depth range scaling (section 2.16.1).
- Flatshading (section 2.21).
- Clipping, including client-defined clip planes (section 2.22).
- Front face determination (section 2.13.1).
- Color, texture coordinate, fog, point-size and generic attribute clipping (section 2.22.1).
- Final color processing (section 2.23).

There are several special considerations for geometry shader execution described in the following sections.
2.15. GEOMETRY SHADERS

Texture Access

The Shader Only Texturing subsection of section 2.14.7 describes texture lookup functionality accessible to a vertex shader. The texel fetch and texture size query functionality described there also applies to geometry shaders.

Geometry Shader Inputs

Section 7.1 of the OpenGL Shading Language Specification describes the built-in variable array `gl_in[]` available as input to a geometry shader. `gl_in[]` receives values from equivalent built-in output variables written by the vertex shader, and each array element of `gl_in[]` is a structure holding values for a specific vertex of the input primitive. The length of `gl_in[]` is determined by the geometry shader input type (see section 2.15.1). The members of each element of the `gl_in[]` array are:

- Structure member `gl_ClipDistance[]` holds the per-vertex array of clip distances, as written by the vertex shader to its built-in output variable `gl_ClipDistance[]`.

- Structure member `gl_ClipVertex` holds the per-vertex position in clip coordinates, as written by the vertex shader to its built-in output variable `gl_ClipVertex`.

- Structure members `gl_FrontColor`, `gl_BackColor`, `gl_FrontSecondaryColor` and `gl_BackSecondaryColor` hold the per-vertex front and back colors of the primary and secondary colors, as written by the vertex shader to the corresponding built-in output variables.

- Structure member `gl_FogFragCoord` holds the per-vertex fog coordinate, as written by the vertex shader to its built-in output variable `gl_FogFragCoord`.

- Structure member `gl_TexCoord[]` holds the per-vertex array of texture coordinates written by the vertex shader to its built-in output varying variable `gl_TexCoord[]`.

- Structure member `gl_PointSize` holds the per-vertex point size written by the vertex shader to its built-in output varying variable `gl_PointSize`. If the vertex shader does not write `gl_PointSize`, the value of `gl_PointSize` is undefined, regardless of the value of the enable `PROGRAM_POINT_SIZE`.
2.15. GEOMETRY SHADERS

- Structure member `gl_Position` holds the per-vertex position, as written by the vertex shader to its built-in output variable `gl_Position`. Note that writing to `gl_Position` from either the vertex or geometry shader is optional (also see section 7.1 of the OpenGL Shading Language Specification).

Geometry shaders also have available the built-in special variable `gl_PrimitiveIDIn`, which is not an array and has no vertex shader equivalent. It is filled with the number of primitives processed since the last time `Begin` was called (directly or indirectly via vertex array functions). The first primitive generated after a `Begin` is numbered zero, and the primitive ID counter is incremented after every individual point, line, or triangle primitive is processed. For triangles drawn in point or line mode, the primitive ID counter is incremented only once, even though multiple points or lines may eventually be drawn. Restarting a primitive topology using the primitive restart index has no effect on the primitive ID counter.

Similarly to the built-in varying variables, each user-defined input varying variable has a value for each vertex and thus needs to be declared as arrays or inside input blocks declared as arrays. Declaring an array size is optional. If no size is specified, it will be inferred by the linker from the input primitive type. If a size is specified, it must match the number of vertices for the input primitive type; otherwise, a link error will occur. The OpenGL Shading Language doesn’t support multi-dimensional arrays; therefore, user-defined geometry shader inputs corresponding to vertex shader outputs declared as arrays must be declared as array members of an input block that is itself declared as an array. See sections 4.3.6 and 7.6 of the OpenGL Shading Language Specification for more information.

Similarly to the limit on vertex shader output components (see section 2.14.6), there is a limit on the number of components of built-in and user-defined input varying variables that can be read by the geometry shader, given by the value of the implementation-dependent constant `MAX_GEOMETRY_INPUT_COMPONENTS`.

When a program is linked, all components of any varying and special variable read by a geometry shader will count against this limit. A program whose geometry shader reads more than the value of `MAX_GEOMETRY_INPUT_COMPONENTS` components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

**Geometry Shader Outputs**

A geometry shader is limited in the number of vertices it may emit per invocation. The maximum number of vertices a geometry shader can possibly emit is specified in the geometry shader source and may be queried after linking by calling
2.15. GEOMETRY SHADERS

GetProgramiv with the symbolic constant GEOMETRY_VERTICES_OUT. If a single invocation of a geometry shader emits more vertices than this value, the emitted vertices may have no effect.

There are two implementation-dependent limits on the value of GEOMETRY_VERTICES_OUT; it may not exceed the value of MAX_GEOMETRY_OUTPUT_VERTICES, and the product of the total number of vertices and the sum of all components of all active varying variables may not exceed the value of MAX_GEOMETRY_TOTAL_OUTPUT_COMPONENTS. LinkProgram will fail if it determines that the total component limit would be violated.

A geometry shader can write to built-in as well as user-defined varying variables. These values are expected to be interpolated across the primitive it outputs, unless they are specified to be flat shaded. To enable seamlessly inserting or removing a geometry shader from a program object, the rules, names and types of the output built-in varying variables and user-defined varying variables are the same as for the vertex shader. Refer to section 2.14.6, and sections 4.3.6, 7.1, and 7.6 of the OpenGL Shading Language Specification for more detail.

After a geometry shader emits a vertex, all built-in and user-defined output variables are undefined, as described in section 8.10 of the OpenGL Shading Language Specification.

The built-in output variables gl_FrontColor, gl_BackColor, gl_FrontSecondaryColor, and gl_BackSecondaryColor hold the front and back colors for the primary and secondary colors for the current vertex.

The built-in output variable gl_TexCoord[] is an array and holds the set of texture coordinates for the current vertex.

The built-in output variable gl_FogFragCoord is used as the c value, as described in section 3.11.

The built-in special variable gl_Position is intended to hold the homogeneous vertex position. Writing gl_Position is optional.

The built-in special variable gl_ClipVertex holds the vertex coordinate used in the clipping stage, as described in section 2.22.

The built-in special variable gl_PointSize, if written, holds the size of the point to be rasterized, measured in pixels.

The built-in special variable gl_PrimitiveID holds the primitive ID counter read by the fragment shader, replacing the value of gl_PrimitiveID generated by drawing commands when no geometry shader is active. The geometry shader must write to gl_PrimitiveID for the provoking vertex (see section 2.21) of a primitive being generated, or the primitive ID counter read by the fragment shader for that primitive is undefined.

The built-in special variable gl_Layer is used in layered rendering, and discussed further in the next section.
Similarly to the limit on vertex shader output components (see section 2.14.6), there is a limit on the number of components of built-in and user-defined output varying variables that can be written by the geometry shader, given by the value of the implementation-dependent constant MAX_GEOMETRY_OUTPUT_COMPONENTS.

When a program is linked, all components of any varying and special variable written by a geometry shader will count against this limit. A program whose geometry shader writes more than the value of MAX_GEOMETRY_OUTPUT_COMPONENTS components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

Layered Rendering

Geometry shaders can be used to render to one of several different layers of cube map textures, three-dimensional textures, or one-or two-dimensional texture arrays. This functionality allows an application to bind an entire complex texture to a framebuffer object, and render primitives to arbitrary layers computed at run time. For example, it can be used to project and render a scene onto all six faces of a cubemap texture in one pass. The layer to render to is specified by writing to the built-in output variable gl_Layer. Layered rendering requires the use of framebuffer objects (see section 4.4.7).

Primitive Type Mismatches and Drawing Commands

A geometry shader will fail to execute if a mismatch exists between the type of primitive being drawn and the input primitive type of the shader. If it cannot be executed then no fragments will be rendered, and the error INVALID_OPERATION will be generated.

This error is generated by Begin, RasterPos, or any command that performs an implicit Begin if a geometry shader is active and:

- the input primitive type of the current geometry shader is POINTS and mode is not POINTS;
- the input primitive type of the current geometry shader is LINES and mode is not LINES, LINE_STRIP, or LINE_LOOP;
- the input primitive type of the current geometry shader is TRIANGLES and mode is not TRIANGLES, TRIANGLE_STRIP or TRIANGLE_FAN;
- the input primitive type of the current geometry shader is LINES_ADJACENCY and mode is not LINES_ADJACENCY or LINE_STRIP_ADJACENCY or LINE_ADJACENCY; or,
• the input primitive type of the current geometry shader is TRIANGLES_ADJACENCY and mode is not TRIANGLES_ADJACENCY or TRIANGLE_STRIP_ADJACENCY.

2.16 Coordinate Transformations

Clip coordinates for a vertex result from fixed-function transformation of the vertex coordinates, or from vertex or, if active, geometry shader execution, which yields a vertex coordinate \( \text{gl}_\text{Position} \). Perspective division on clip coordinates yields normalized device coordinates, followed by a viewport transformation to convert these coordinates into window coordinates.

If a vertex in clip coordinates is given by

\[
\begin{pmatrix}
x_c \\
y_c \\
z_c \\
w_c
\end{pmatrix}
\]

then the vertex’s normalized device coordinates are

\[
\begin{pmatrix}
x_d \\
y_d \\
z_d
\end{pmatrix} = \begin{pmatrix}
x_c \\
y_c \\
z_c
\end{pmatrix}
\]

2.16.1 Controlling the Viewport

The viewport transformation is determined by the viewport’s width and height in pixels, \( p_x \) and \( p_y \), respectively, and its center \((o_x, o_y)\) (also in pixels). The vertex’s window coordinates, \( \begin{pmatrix} x_w \\ y_w \\ z_w \end{pmatrix} \), are given by

\[
\begin{pmatrix}
x_w \\
y_w \\
z_w
\end{pmatrix} = \begin{pmatrix}
\frac{p_x}{2} x_d + o_x \\
\frac{p_y}{2} y_d + o_y \\
\frac{n}{2} z_d + \frac{n+f}{2}
\end{pmatrix}
\]

The factor and offset applied to \( z_d \) encoded by \( n \) and \( f \) are set using

\[
\text{void DepthRange(clampd n, clampdf)};
\]

\( z_w \) is represented as either fixed- or floating-point depending on whether the framebuffer’s depth buffer uses a fixed- or floating-point representation. If the depth buffer uses fixed-point, we assume that it represents each value \( k/(2^m - 1) \), where \( k \in \{0, 1, \ldots, 2^m - 1\} \), as \( k \) (e.g. 1.0 is represented in binary as a string of all
2.17. ASYNCHRONOUS QUERIES

ones). The parameters \( n \) and \( f \) are clamped to the range \([0, 1]\), as are all arguments of type \texttt{clampd} or \texttt{clampf}.

Viewport transformation parameters are specified using

\[
\text{void \ Viewport(int} \; x, \; \text{int} \; y, \; \text{sizei} \; w, \; \text{sizei} \; h)\;
\]

where \( x \) and \( y \) give the \( x \) and \( y \) window coordinates of the viewport’s lower left corner and \( w \) and \( h \) give the viewport’s width and height, respectively. The viewport parameters shown in the above equations are found from these values as

\[
\begin{align*}
o_x &= x + \frac{w}{2} \\
o_y &= y + \frac{h}{2} \\
p_x &= w \\
p_y &= h.
\end{align*}
\]

Viewport width and height are clamped to implementation-dependent maximums when specified. The maximum width and height may be found by issuing an appropriate \texttt{Get} command (see chapter 6). The maximum viewport dimensions must be greater than or equal to the larger of the visible dimensions of the display being rendered to (if a display exists), and the largest renderbuffer image which can be successfully created and attached to a framebuffer object (see chapter 4). \texttt{INVALID\_VALUE} is generated if either \( w \) or \( h \) is negative.

The state required to implement the viewport transformation is four integers and two clamped floating-point values. In the initial state, \( w \) and \( h \) are set to the width and height, respectively, of the window into which the GL is to do its rendering. If the default framebuffer is bound but no default framebuffer is associated with the GL context (see chapter 4), then \( w \) and \( h \) are initially set to zero. \( o_x, o_y, n, \) and \( f \) are set to \( \frac{w}{2}, \frac{h}{2}, 0.0, \) and \( 1.0, \) respectively.

2.17 Asynchronous Queries

Asynchronous queries provide a mechanism to return information about the processing of a sequence of GL commands. There are three query types supported by the GL. Primitive queries with a target of \texttt{PRIMITIVES\_GENERATED} (see section 2.20) return information on the number of primitives processed by the GL. Primitive queries with a target of \texttt{TRANSFORM\_FEEDBACK\_PRIMITIVES\_WRITTEN} (see section 2.20) return information on the number of primitives written to one or more buffer objects. Occlusion queries (see section 4.1.7) count the number of fragments or samples that pass the depth test.

The results of asynchronous queries are not returned by the GL immediately after the completion of the last command in the set; subsequent commands can

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
be processed while the query results are not complete. When available, the query results are stored in an associated query object. The commands described in section 6.1.12 provide mechanisms to determine when query results are available and return the actual results of the query. The name space for query objects is the unsigned integers, with zero reserved by the GL.

Each type of query supported by the GL has an active query object name. If the active query object name for a query type is non-zero, the GL is currently tracking the information corresponding to that query type and the query results will be written into the corresponding query object. If the active query object for a query type name is zero, no such information is being tracked.

A query object is created and made active by calling

```c
void BeginQuery( enum target, uint id );
```

target indicates the type of query to be performed; valid values of target are defined in subsequent sections. If id is an unused query object name, the name is marked as used and associated with a new query object of the type specified by target. Otherwise id must be the name of an existing query object of that type.

BeginQuery sets the active query object name for the query type given by target to id. If BeginQuery is called with an id of zero, if the active query object name for target is non-zero, if id is the name of an existing query object whose type does not match target, if id is the active query object name for any query type, or if id is the active query object for conditional rendering (see section 2.18), the error INVALID_OPERATION is generated.

The command

```c
void EndQuery( enum target );
```

marks the end of the sequence of commands to be tracked for the query type given by target. The active query object for target is updated to indicate that query results are not available, and the active query object name for target is reset to zero. When the commands issued prior to EndQuery have completed and a final query result is available, the query object active when EndQuery is called is updated by the GL. The query object is updated to indicate that the query results are available and to contain the query result. If the active query object name for target is zero when EndQuery is called, the error INVALID_OPERATION is generated.

The command

```c
void GenQueries( sizei n, uint *ids );
```
returns $n$ previously unused query object names in $\text{id}s$. These names are marked as used, but no object is associated with them until the first time they are used by \texttt{BeginQuery}.

Query objects are deleted by calling

\begin{verbatim}
void DeleteQueries( sizei $n$, const uint *$\text{id}s );
\end{verbatim}

$id$s contains $n$ names of query objects to be deleted. After a query object is deleted, its name is again unused. Unused names in $\text{id}s$ are silently ignored.

Query objects contain two pieces of state: a single bit indicating whether a query result is available, and an integer containing the query result value. The number of bits used to represent the query result is implementation-dependent. In the initial state of a query object, the result is available and its value is zero.

The necessary state for each query type is an unsigned integer holding the active query object name (zero if no query object is active), and any state necessary to keep the current results of an asynchronous query in progress.

### 2.18 Conditional Rendering

Conditional rendering can be used to discard rendering commands based on the result of an occlusion query. Conditional rendering is started and stopped using the commands

\begin{verbatim}
void BeginConditionalRender( uint $\text{id}$, enum $\text{mode}$ );
void EndConditionalRender( void );
\end{verbatim}

$id$ specifies the name of an occlusion query object whose results are used to determine if the rendering commands are discarded. If the result (\text{SAMPLES\_PASSED}) of the query is zero, all rendering commands between \texttt{BeginConditionalRender} and the corresponding \texttt{EndConditionalRender} are discarded. In this case, \texttt{Begin}, \texttt{End}, all vertex array commands (see section 2.8) performing an implicit \texttt{Begin} and \texttt{End}, \texttt{DrawPixels} (see section 3.7.5), \texttt{Bitmap} (see section 3.8), \texttt{Accum} (see section 4.2.4), \texttt{EvalMesh1} and \texttt{EvalMesh2} (see section 5.1), and \texttt{CopyPixels} (see section 4.3.3), as well as \texttt{Clear} and \texttt{ClearBuffer*} (see section 4.2.3), have no effect. The effect of commands setting current vertex state, such as \texttt{Color} or \texttt{VertexAttrib}, are undefined. If the result of the occlusion query is non-zero, such commands are not discarded.

$\text{mode}$ specifies how \texttt{BeginConditionalRender} interprets the results of the occlusion query given by $\text{id}$. If $\text{mode}$ is \texttt{QUERY\_WAIT}, the GL waits for the results of
the query to be available and then uses the results to determine if subsequent rendering commands are discarded. If \textit{mode} is \texttt{QUERY\_NO\_WAIT}, the GL may choose to unconditionally execute the subsequent rendering commands without waiting for the query to complete.

If \textit{mode} is \texttt{QUERY\_BY\_REGION\_WAIT}, the GL will also wait for occlusion query results and discard rendering commands if the result of the occlusion query is zero. If the query result is non-zero, subsequent rendering commands are executed, but the GL may discard the results of the commands for any region of the framebuffer that did not contribute to the sample count in the specified occlusion query. Any such discarding is done in an implementation-dependent manner, but the rendering command results may not be discarded for any samples that contributed to the occlusion query sample count. If \textit{mode} is \texttt{QUERY\_BY\_REGION\_NO\_WAIT}, the GL operates as in \texttt{QUERY\_BY\_REGION\_WAIT}, but may choose to unconditionally execute the subsequent rendering commands without waiting for the query to complete.

If \texttt{BeginConditionalRender} is called while conditional rendering is in progress, or if \texttt{EndConditionalRender} is called while conditional rendering is not in progress, the error \texttt{INVALID\_OPERATION} is generated. The error \texttt{INVALID\_VALUE} is generated if \textit{id} is not the name of an existing query object. The error \texttt{INVALID\_OPERATION} is generated if \textit{id} is the name of a query object with a target other than \texttt{SAMPLES\_PASSED}, or \textit{id} is the name of a query currently in progress.

### 2.19 Transform Feedback

In transform feedback mode, attributes of the vertices of transformed primitives processed by a vertex shader, or primitives generated by a geometry shader if one is active, are written out to one or more buffer objects. The vertices are fed back after vertex color clamping, but before flatshading and clipping. If a geometry shader is active, the vertices recorded are those emitted from the geometry shader. The transformed vertices may be optionally discarded after being stored into one or more buffer objects, or they can be passed on down to the clipping stage for further processing. The set of attributes captured is determined when a program is linked.

Transform feedback is started and finished by calling

```c
void BeginTransformFeedback( enum primitiveMode );
```

and

```c
void EndTransformFeedback( void );
```
2.19. TRANSFORM FEEDBACK

Table 2.14: Legal combinations of the transform feedback primitive mode, as passed to `BeginTransformFeedback`, and the current primitive mode.

respectively. Transform feedback is said to be active after a call to `BeginTransformFeedback` and inactive after a call to `EndTransformFeedback`. `primitiveMode` is one of `TRIANGLES`, `LINES`, or `POINTS`, and specifies the output type of primitives that will be recorded into the buffer objects bound for transform feedback (see below). `primitiveMode` restricts the primitive types that may be rendered while transform feedback is active, as shown in table 2.14.

Transform feedback commands must be paired: the error `INVALID_OPERATION` is generated by `BeginTransformFeedback` if transform feedback is active, and by `EndTransformFeedback` if transform feedback is inactive.

Transform feedback mode captures the values of varying variables written by an active vertex or geometry shader. The error `INVALID_OPERATION` is generated by `BeginTransformFeedback` if no vertex or geometry shader is active.

When transform feedback is active, all geometric primitives generated must be compatible with the value of `primitiveMode` passed to `BeginTransformFeedback`. The error `INVALID_OPERATION` is generated by `Begin` or any operation that implicitly calls `Begin` (such as `DrawElements`) if `mode` is not one of the allowed modes in table 2.14. If a geometry shader is active, its output `primitive` type is used instead of the `mode` parameter passed to drawing commands.

Regions of buffer objects are bound as the targets of transform feedback by calling one of the commands `BindBufferRange` or `BindBufferBase` (see section 2.9.1) with `target` set to `TRANSFORM_FEEDBACK_BUFFER`. In addition to the general errors described in section 2.9.1, `BindBufferRange` will generate an `INVALID_VALUE` error if `index` is greater than or equal to the value of `MAX_TRANSFORM_FEEDBACK_SEPARATE_ATTRIBS`, or if `offset` is not a multiple of 4.

When an individual point, line, or triangle primitive reaches the transform feedback stage while transform feedback is active, the values of the specified varying variables of the vertex are appended to the buffer objects bound to the transform feedback binding points. The attributes of the first vertex received after `Begin-
TransformFeedback are written at the starting offsets of the bound buffer objects set by BindBufferRange, and subsequent vertex attributes are appended to the buffer object. When capturing line and triangle primitives, all attributes of the first vertex are written first, followed by attributes of the subsequent vertices. When writing varying variables that are arrays, individual array elements are written in order. For multi-component varying variables or varying array elements, the individual components are written in order. The value for any attribute specified to be streamed to a buffer object but not actually written by a vertex or geometry shader is undefined.

When quads and polygons are provided to transform feedback with a primitive mode of TRIANGLES, they will be tessellated and recorded as triangles (the order of tessellation within a primitive is undefined). Individual lines or triangles of a strip or fan primitive will be extracted and recorded separately. Incomplete primitives are not recorded.

Transform feedback can operate in either INTERLEAVED_ATTRIBS or SEPARATE_ATTRIBS mode. In INTERLEAVED_ATTRIBS mode, the values of one or more varyings are written, interleaved, into the buffer object bound to the first transform feedback binding point (index = 0). If more than one varying variable is written, they will be recorded in the order specified by TransformFeedbackVaryings (see section 2.14.6). In SEPARATE_ATTRIBS mode, the first varying variable specified by TransformFeedbackVaryings is written to the first transform feedback binding point; subsequent varying variables are written to the subsequent transform feedback binding points. The total number of variables that may be captured in separate mode is given by MAX_TRANSFORM_FEEDBACK_SEPARATE_ATTRIBS.

If recording the vertices of a primitive to the buffer objects being used for transform feedback purposes would result in either exceeding the limits of any buffer object’s size, or in exceeding the end position offset + size − 1, as set by BindBufferRange, then no vertices of that primitive are recorded in any buffer object, and the counter corresponding to the asynchronous query target TRANSFORM_FEEDBACK_PRIMITIVES_WRITTEN (see section 2.20) is not incremented.

In either separate or interleaved modes, all transform feedback binding points that will be written to must have buffer objects bound when BeginTransformFeedback is called. The error INVALID_OPERATION is generated by BeginTransformFeedback if any binding point used in transform feedback mode does not have a buffer object bound. In interleaved mode, only the first buffer object binding point is ever written to. The error INVALID_OPERATION is also generated by BeginTransformFeedback if no binding points would be used, either because no program object is active or because the active program object has specified no varying variables to record.
While transform feedback is active, the set of attached buffer objects and the set of varying variables captured may not be changed. If transform feedback is active, the error `INVALID_OPERATION` is generated by `UseProgram`, by `LinkProgram` if `program` is the currently active program object, and by `BindBufferRange` or `BindBufferBase` if `target` is `TRANSFORM_FEEDBACK_BUFFER`.

Buffers should not be bound or in use for both transform feedback and other purposes in the GL. Specifically, if a buffer object is simultaneously bound to a transform feedback buffer binding point and elsewhere in the GL, any writes to or reads from the buffer generate undefined values. Examples of such bindings include `DrawPixels` and `ReadPixels` to a pixel buffer object binding point and client access to a buffer mapped with `MapBuffer`.

However, if a buffer object is written and read sequentially by transform feedback and other mechanisms, it is the responsibility of the GL to ensure that data are accessed consistently, even if the implementation performs the operations in a pipelined manner. For example, `MapBuffer` may need to block pending the completion of a previous transform feedback operation.

## 2.20 Primitive Queries

Primitive queries use query objects to track the number of primitives generated by the GL and to track the number of primitives written to transform feedback buffers.

When `BeginQuery` is called with a `target` of `PRIMITIVES_GENERATED`, the primitives-generated count maintained by the GL is set to zero. When the generated primitive query is active, the primitives-generated count is incremented every time a primitive reaches the “Discarding Primitives Before Rasterization” stage (see section 3.1) immediately before rasterization. This counter counts the number of primitives emitted by a geometry shader, if active, possibly further tessellated into separate primitives during the transform-feedback stage, if enabled.

When `BeginQuery` is called with a `target` of `TRANSFORM_FEEDBACK_PRIMITIVES_WRITTEN`, the transform-feedback-primitives-written count maintained by the GL is set to zero. When the transform feedback primitive written query is active, the transform-feedback-primitives-written count is incremented every time a primitive is recorded into a buffer object. If transform feedback is not active, this counter is not incremented. If the primitive does not fit in the buffer object, the counter is not incremented.

These two queries can be used together to determine if all primitives have been written to the bound feedback buffers; if both queries are run simultaneously and the query results are equal, all primitives have been written to the buffer(s). If the number of primitives written is less than the number of primitives generated, the
2.21. FLATSHADING

buffer is full.

2.21 Flatshading

For fixed-function vertex processing, flatshading a primitive means to assign all vertices of the primitive the same primary and secondary colors (in RGBA mode) or the same color index (in color index mode). If a vertex shader is active, flatshading a varying output means to assign all vertices of the primitive the same value for that output.

The color and/or varying output values assigned are those of the provoking vertex of the primitive. The provoking vertex is controlled with the command

```c
void ProvokingVertex(enum provokeMode);
```

`provokeMode` must be either `FIRST_VERTEX_CONVENTION` or `LAST_VERTEX_CONVENTION`, and controls selection of the vertex whose values are assigned to flatshaded colors and varying outputs, as shown in table 2.15

The provoking vertex behavior of quad primitives is implementation dependent, and may be determined by calling `GetBooleanv` with the symbolic constant `QUADS_FOLLOW_PROVOKING_VERTEX`. A return value of `TRUE` indicates that the provoking vertex mode is respected for quad primitives, while a return value of `FALSE` indicates that the implementation always behave as though the provoking vertex mode were `LAST_VERTEX_CONVENTION`.

Flatshading of colors in fixed-function vertex processing, and of the built-in varying variables `gl_FrontColor`, `gl_BackColor`, `gl_FrontSecondaryColor` and `gl_BackSecondaryColor` when a vertex shader is active, is controlled with the command

```c
void ShadeModel(enum mode);
```

`mode` must be `SMOOTH` or `FLAT`. If `mode` is `SMOOTH`, vertex colors are treated individually. If `mode` is `FLAT`, flatshading is enabled and colors are taken from the provoking vertex of the primitive. The colors selected are those derived from current values, generated by lighting, or generated by vertex shading, if lighting is disabled, enabled, or a vertex shader is in use, respectively.

If a vertex or geometry shader is active, user-defined varying outputs may be flatshaded by using the `flat` qualifier when declaring the output, as described in section 4.3.6 of the OpenGL Shading Language Specification.

The state required for flatshading is one bit for the shade mode, one bit for the provoking vertex mode, and one implementation-dependent bit for the provoking vertex.

Table 2.15: Provoking vertex selection. The vertex colors and/or varying values used for flatshading the $i$th primitive generated by the indicated Begin/End type are derived from the corresponding values of the vertex whose index is shown in the table. Vertices are numbered 1 through $n$, where $n$ is the number of vertices between the Begin/End pair.

1 If the value of QUADS_FOLLOW_PROVOKING_VERTEX is TRUE.
2 If the value of QUADS_FOLLOW_PROVOKING_VERTEX is FALSE.
2.22. PRIMITIVE CLIPPING

vertex behavior of quad primitives. The initial value of the shade mode is SMOOTH and the initial value of the provoking vertex mode is LAST_VERTEX_CONVENTION.

2.22 Primitive Clipping

Primitives are clipped to the *clip volume*. In clip coordinates, the *view volume* is defined by

\[
-w_c \leq x_c \leq w_c \\
-w_c \leq y_c \leq w_c \\
-w_c \leq z_c \leq w_c.
\]

This view volume may be further restricted by as many as \( n \) client-defined clip planes to generate the clip volume. Each client-defined plane specifies a half-space. (\( n \) is an implementation-dependent maximum that must be at least 8.) The clip volume is the intersection of all such half-spaces with the view volume (if no client-defined clip planes are enabled, the clip volume is the view volume).

A client-defined clip plane is specified with

```c
void ClipPlane(enum p, double eqn[4];
```

The value of the first argument, \( p \), is a symbolic constant, `CLIP_PLANEi`, where \( i \) is an integer between 0 and \( n - 1 \), indicating one of \( n \) client-defined clip planes. \( eqn \) is an array of four double-precision floating-point values. These are the coefficients of a plane equation in object coordinates: \( p_1, p_2, p_3, \) and \( p_4 \) (in that order). The inverse of the current model-view matrix is applied to these coefficients, at the time they are specified, yielding

\[
(p'_1 \ p'_2 \ p'_3 \ p'_4) = (p_1 \ p_2 \ p_3 \ p_4)^{-1}
\]

(where \( M \) is the current model-view matrix; the resulting plane equation is undefined if \( M \) is singular and may be inaccurate if \( M \) is poorly-conditioned) to obtain the plane equation coefficients in eye coordinates. All points with eye coordinates \((x_e \ y_e \ z_e \ w_e)^T\) that satisfy

\[
(p'_1 \ p'_2 \ p'_3 \ p'_4)\begin{pmatrix} x_e \\ y_e \\ z_e \\ w_e \end{pmatrix} \geq 0
\]

lie in the half-space defined by the plane; points that do not satisfy this condition do not lie in the half-space.
When a vertex shader is active, the vector \((x_e \ y_e \ z_e \ w_e)^T\) is no longer computed. Instead, the value of the \texttt{gl_ClipVertex} built-in variable is used in its place. If \texttt{gl_ClipVertex} is not written by the vertex shader, its value is undefined, which implies that the results of clipping to any client-defined clip planes are also undefined. The user must ensure that the clip vertex and client-defined clip planes are defined in the same coordinate space.

A vertex shader may, instead of writing to \texttt{gl_ClipVertex} write a single clip distance for each supported clip plane to elements of the \texttt{gl_ClipDistance[]} array. The half-space corresponding to clip plane \(n\) is then given by the set of points satisfying the inequality

\[
c_n(P) \geq 0,
\]

where \(c_n(P)\) is the value of clip distance \(n\) at point \(P\). For point primitives, \(c_n(P)\) is simply the clip distance for the vertex in question. For line and triangle primitives, per-vertex clip distances are interpolated using a weighted mean, with weights derived according to the algorithms described in sections 3.5 and 3.6.

Client-defined clip planes are enabled with the generic \texttt{Enable} command and disabled with the \texttt{Disable} command. The value of the argument to either command is \texttt{CLIP_DISTANCE\(i\)}, where \(i\) is an integer between 0 and \(n - 1\); specifying a value of \(i\) enables or disables the plane equation with index \(i\). The constants obey \texttt{CLIP_DISTANCE\(i\) = CLIP_DISTANCE0 + \(i\)}.

Depth clamping is enabled with the generic \texttt{Enable} command and disabled with the \texttt{Disable} command. The value of the argument to either command is \texttt{DEPTH_CLAMP}. If depth clamping is enabled, the

\[-w_c \leq z_c \leq w_c\]

plane equation is ignored by view volume clipping (effectively, there is no near or far plane clipping).

If the primitive under consideration is a point, then clipping passes it unchanged if it lies within the clip volume; otherwise, it is discarded.

If the primitive is a line segment, then clipping does nothing to it if it lies entirely within the clip volume, and discards it if it lies entirely outside the volume.

If part of the line segment lies in the volume and part lies outside, then the line segment is clipped and new vertex coordinates are computed for one or both vertices. A clipped line segment endpoint lies on both the original line segment and the boundary of the clip volume.

This clipping produces a value, \(0 \leq t \leq 1\), for each clipped vertex. If the coordinates of a clipped vertex are \(P\) and the original vertices’ coordinates are \(P_1\)
and $P_2$, then $t$ is given by

$$P = tP_1 + (1 - t)P_2.$$  

The value of $t$ is used to clip color, secondary color, texture coordinate, fog coordinate, and vertex shader varying variables as described in section 2.22.1.

If the primitive is a polygon, then it is passed if every one of its edges lies entirely inside the clip volume and either clipped or discarded otherwise. Polygon clipping may cause polygon edges to be clipped, but because polygon connectivity must be maintained, these clipped edges are connected by new edges that lie along the clip volume’s boundary. Thus, clipping may require the introduction of new vertices into a polygon. Edge flags are associated with these vertices so that edges introduced by clipping are flagged as boundary (edge flag TRUE), and so that original edges of the polygon that become cut off at these vertices retain their original flags.

If it happens that a polygon intersects an edge of the clip volume’s boundary, then the clipped polygon must include a point on this boundary edge. This point must lie in the intersection of the boundary edge and the convex hull of the vertices of the original polygon. We impose this requirement because the polygon may not be exactly planar.

Primitives rendered with user-defined clip planes must satisfy a complementarity criterion. Suppose a single clip plane with coefficients $(p'_1, p'_2, p'_3, p'_4)$ (or a number of similarly specified clip planes) is enabled and a series of primitives are drawn. Next, suppose that the original clip plane is respecified with coefficients $(-p'_1, -p'_2, -p'_3, -p'_4)$ (and correspondingly for any other clip planes) and the primitives are drawn again (and the GL is otherwise in the same state). In this case, primitives must not be missing any pixels, nor may any pixels be drawn twice in regions where those primitives are cut by the clip planes.

The state required for clipping is at least 8 bits indicating which of the client-defined plane equations are enabled, and at least 8 corresponding sets of plane equations (each consisting of four double-precision floating-point coefficients). In the initial state, all plane equations are disabled and all client-defined plane equation coefficients are zero.

### 2.22.1 Color and Associated Data Clipping

After lighting, clamping or masking and possible flatshading, colors are clipped. Those colors associated with a vertex that lies within the clip volume are unaffected by clipping. If a primitive is clipped, however, the colors assigned to vertices produced by clipping are clipped.
Let the colors assigned to the two vertices $P_1$ and $P_2$ of an unclipped edge be $c_1$ and $c_2$. The value of $t$ (section 2.22) for a clipped point $P$ is used to obtain the color associated with $P$ as

$$c = tc_1 + (1 - t)c_2.$$  

(For a color index color, multiplying a color by a scalar means multiplying the index by the scalar. For an RGBA color, it means multiplying each of R, G, B, and A by the scalar. Both primary and secondary colors are treated in the same fashion.)

Polygon clipping may create a clipped vertex along an edge of the clip volume’s boundary. This situation is handled by noting that polygon clipping proceeds by clipping against one plane of the clip volume’s boundary at a time. Color clipping is done in the same way, so that clipped points always occur at the intersection of polygon edges (possibly already clipped) with the clip volume’s boundary.

Texture and fog coordinates, vertex shader varying variables (section 2.14.6), and point sizes computed on a per vertex basis must also be clipped when a primitive is clipped. The method is exactly analogous to that used for color clipping.

For vertex shader varying variables specified to be interpolated without perspective correction (using the `noperspective` qualifier), the value of $t$ used to obtain the varying value associated with $P$ will be adjusted to produce results that vary linearly in screen space.

Varying outputs of integer or unsigned integer type must always be declared with the `flat` qualifier. Since such varyings are constant over the primitive being rasterized (see sections 3.5.1 and 3.6.1), no interpolation is performed.

### 2.23 Final Color Processing

In RGBA mode with vertex color clamping disabled, the floating-point RGBA components are not modified.

In RGBA mode with vertex color clamping enabled, each color component may be converted to a signed or unsigned normalized fixed-point value as described in equations 2.4 and 2.6 (depending on the framebuffer format).

GL implementations are not required to convert clamped color components to fixed-point.

Because a number of the form $k/(2^m - 1)$ may not be represented exactly as a limited-precision floating-point quantity, we place a further requirement on the fixed-point conversion of RGBA components. Suppose that lighting is disabled, the color associated with a vertex has not been clipped, and one of `Colorub`, `Colorus`, or `Colorui` was used to specify that color. When these conditions are satisfied, an
2.24. CURRENT RASTER POSITION

RGBA component must convert to a value that matches the component as specified in the Color command: if \( m \) is less than the number of bits \( b \) with which the component was specified, then the converted value must equal the most significant \( m \) bits of the specified value; otherwise, the most significant \( b \) bits of the converted value must equal the specified value.

A color index is converted (by rounding to nearest) to a fixed-point value with at least as many bits as there are in the color index portion of the framebuffer.

2.24 Current Raster Position

The current raster position is used by commands that directly affect pixels in the framebuffer. These commands, which bypass vertex transformation and primitive assembly, are described in the next chapter. The current raster position, however, shares some of the characteristics of a vertex.

The current raster position is set using one of the commands

\[
\begin{align*}
\text{void RasterPos4}\{\text{234}\}\{\text{sfid}\}(\text{Tcoords}); \\
\text{void RasterPos3}\{\text{234}\}\{\text{sfid}\}\text{v}(\text{Tcoords});
\end{align*}
\]

RasterPos4 takes four values indicating \( x, y, z, \) and \( w \). RasterPos3 (or RasterPos2) is analogous, but sets only \( x, y, \) and \( z \) with \( w \) implicitly set to 1 (or only \( x \) and \( y \) with \( z \) implicitly set to 0 and \( w \) implicitly set to 1).

Gets of CURRENT_RASTER_TEXTURE_COORDS are affected by the setting of the state ACTIVE_TEXTURE.

The coordinates are treated as if they were specified in a Vertex command. If a vertex shader is active, this vertex shader is executed using the \( x, y, z, \) and \( w \) coordinates as the object coordinates of the vertex. Otherwise, the \( x, y, z, \) and \( w \) coordinates are transformed by the current model-view and projection matrices. These coordinates, along with current values, are used to generate primary and secondary colors and texture coordinates just as is done for a vertex. The colors and texture coordinates so produced replace the colors and texture coordinates stored in the current raster position’s associated data. If a vertex shader is active then the current raster distance is set to the value of the shader built in varying gl_FogFragCoord. Otherwise, if the value of the fog source (see section 3.11) is FOG_COORD, then the current raster distance is set to the value of the current fog coordinate. Otherwise, the current raster distance is set to the distance from the origin of the eye coordinate system to the vertex as transformed by only the current model-view matrix. This distance may be approximated as discussed in section 3.11.
If depth clamping (see section 2.22) is enabled, then raster position \( z_w \) is first clamped to the range \([\min(n, f), \max(n, f)]\), where \( n \) and \( f \) are the current near and far depth range values (see section 2.16.1).

Since vertex shaders may be executed when the raster position is set, any attributes not written by the shader will result in undefined state in the current raster position. Vertex shaders should output all varying variables that would be used when rasterizing pixel primitives using the current raster position.

The transformed coordinates are passed to clipping as if they represented a point. If the “point” is not culled, then the projection to window coordinates is computed (section 2.16) and saved as the current raster position, and the valid bit is set. If the “point” is culled, the current raster position and its associated data become indeterminate and the valid bit is cleared. Figure 2.13 summarizes the behavior of the current raster position.

Alternately, the current raster position may be set by one of the `WindowPos` commands:

```c
void WindowPos{23}{sifd}( T coords );
void WindowPos{23}{sifd}v( const T coords );
```

`WindowPos3` takes three values indicating \( x, y \) and \( z \), while `WindowPos2` takes two values indicating \( x \) and \( y \) with \( z \) implicitly set to 0. The current raster position, \((x_w, y_w, z_w, w_c)\), is defined by:

\[
\begin{align*}
x_w &= x \\
y_w &= y \\
z_w &= \begin{cases} n, & z \leq 0 \\ f, & z \geq 1 \\ n + z(f - n), & \text{otherwise} \end{cases} \\
w_c &= 1
\end{align*}
\]

where \( n \) and \( f \) are the values passed to `DepthRange` (see section 2.16.1).

Lighting, texture coordinate generation and transformation, and clipping are not performed by the `WindowPos` functions. Instead, in RGBA mode, the current raster color and secondary color are obtained from the current color and secondary color, respectively. If vertex color clamping is enabled, the current raster color and secondary color are clamped to \([0, 1]\). In color index mode, the current raster color index is set to the current color index. The current raster texture coordinates are set to the current texture coordinates, and the valid bit is set.
Figure 2.13. The current raster position and how it is set. Four texture units are shown; however, multitexturing may support a different number of units depending on the implementation.
If the value of the fog source is FOG_COORD_SRC, then the current raster distance is set to the value of the current fog coordinate. Otherwise, the raster distance is set to 0.

The current raster position requires six single-precision floating-point values for its $x_w$, $y_w$, and $z_w$ window coordinates, its $w_c$ clip coordinate, its raster distance (used as the fog coordinate in raster processing), a single valid bit, four floating-point values to store the current RGBA color, four floating-point values to store the current RGBA secondary color, one floating-point value to store the current color index, and 4 floating-point values for texture coordinates for each texture unit. In the initial state, the coordinates and texture coordinates are all $(0, 0, 0, 1)$, the eye coordinate distance is 0, the valid bit is set, the associated RGBA color is $(1, 1, 1, 1)$, the associated RGBA secondary color is $(0, 0, 0, 1)$, and the associated color index color is 1. In RGBA mode, the associated color index always has its initial value; in color index mode, the RGBA color and secondary color always maintain their initial values.
Chapter 3

Rasterization

Rasterization is the process by which a primitive is converted to a two-dimensional image. Each point of this image contains such information as color and depth. Thus, rasterizing a primitive consists of two parts. The first is to determine which squares of an integer grid in window coordinates are occupied by the primitive. The second is assigning a depth value and one or more color values to each such square. The results of this process are passed on to the next stage of the GL (per-fragment operations), which uses the information to update the appropriate locations in the framebuffer. Figure 3.1 diagrams the rasterization process. The color values assigned to a fragment are initially determined by the rasterization operations (sections 3.4 through 3.8) and modified by either the execution of the texturing, color sum, and fog operations defined in sections 3.9, 3.10, and 3.11, or by a fragment shader as defined in section 3.12. The final depth value is initially determined by the rasterization operations and may be modified or replaced by a fragment shader. The results from rasterizing a point, line, polygon, pixel rectangle or bitmap can be routed through a fragment shader.

A grid square along with its \( z \) (depth) and assigned colors, fog coordinate, and texture coordinates, or varying shader output parameters is called a fragment; the parameters are collectively dubbed the fragment’s associated data. A fragment is located by its lower left corner, which lies on integer grid coordinates. Rasterization operations also refer to a fragment’s center, which is offset by \((1/2, 1/2)\) from its lower left corner (and so lies on half-integer coordinates).

Grid squares need not actually be square in the GL. Rasterization rules are not affected by the actual aspect ratio of the grid squares. Display of non-square grids, however, will cause rasterized points and line segments to appear fatter in one direction than the other. We assume that fragments are square, since it simplifies antialiasing and texturing.
Figure 3.1. Rasterization.
3.1. DISCARDING PRIMITIVES BEFORE RASTERIZATION

Several factors affect rasterization. Primitives may be discarded before rasterization. Lines and polygons may be stippled. Points may be given differing diameters and line segments differing widths. A point, line segment, or polygon may be antialiased.

3.1 Discarding Primitives Before Rasterization

Primitives can be optionally discarded before rasterization by calling Enable and Disable with RASTERIZER_DISCARD. When enabled, primitives are discarded immediately before the rasterization stage, but after the optional transform feedback stage (see section 2.19). When disabled, primitives are passed through to the rasterization stage to be processed normally. When enabled, RASTERIZER_DISCARD also causes the Accum, Bitmap, CopyPixels, DrawPixels, Clear, and ClearBuffer* commands to be ignored.

3.2 Invariance

Consider a primitive $p'$ obtained by translating a primitive $p$ through an offset $(x, y)$ in window coordinates, where $x$ and $y$ are integers. As long as neither $p'$ nor $p$ is clipped, it must be the case that each fragment $f'$ produced from $p'$ is identical to a corresponding fragment $f$ from $p$ except that the center of $f'$ is offset by $(x, y)$ from the center of $f$.

3.3 Antialiasing

Antialiasing of a point, line, or polygon is effected in one of two ways depending on whether the GL is in RGBA or color index mode.

In RGBA mode, the R, G, and B values of the rasterized fragment are left unaffected, but the A value is multiplied by a floating-point value in the range [0, 1] that describes a fragment’s screen pixel coverage. The per-fragment stage of the GL can be set up to use the A value to blend the incoming fragment with the corresponding pixel already present in the framebuffer.

In color index mode, the least significant $b$ bits (to the left of the binary point) of the color index are used for antialiasing: $b = \min\{4, m\}$, where $m$ is the number of bits in the color index portion of the framebuffer. The antialiasing process sets these $b$ bits based on the fragment’s coverage value: the bits are set to zero for no coverage and to all ones for complete coverage.
The details of how antialiased fragment coverage values are computed are difficult to specify in general. The reason is that high-quality antialiasing may take into account perceptual issues as well as characteristics of the monitor on which the contents of the framebuffer are displayed. Such details cannot be addressed within the scope of this document. Further, the coverage value computed for a fragment of some primitive may depend on the primitive’s relationship to a number of grid squares neighboring the one corresponding to the fragment, and not just on the fragment’s grid square. Another consideration is that accurate calculation of coverage values may be computationally expensive; consequently we allow a given GL implementation to approximate true coverage values by using a fast but not entirely accurate coverage computation.

In light of these considerations, we chose to specify the behavior of exact antialiasing in the prototypical case that each displayed pixel is a perfect square of uniform intensity. The square is called a fragment square and has lower left corner \((x, y)\) and upper right corner \((x+1, y+1)\). We recognize that this simple box filter may not produce the most favorable antialiasing results, but it provides a simple, well-defined model.

A GL implementation may use other methods to perform antialiasing, subject to the following conditions:

1. If \(f_1\) and \(f_2\) are two fragments, and the portion of \(f_1\) covered by some primitive is a subset of the corresponding portion of \(f_2\) covered by the primitive, then the coverage computed for \(f_1\) must be less than or equal to that computed for \(f_2\).

2. The coverage computation for a fragment \(f\) must be local: it may depend only on \(f\)’s relationship to the boundary of the primitive being rasterized. It may not depend on \(f\)’s \(x\) and \(y\) coordinates.

Another property that is desirable, but not required, is:

3. The sum of the coverage values for all fragments produced by rasterizing a particular primitive must be constant, independent of any rigid motions in window coordinates, as long as none of those fragments lies along window edges.

In some implementations, varying degrees of antialiasing quality may be obtained by providing GL hints (section 5.7), allowing a user to make an image quality versus speed tradeoff.
3.3. ANTIALIASING

3.3.1 Multisampling

Multisampling is a mechanism to antialias all GL primitives: points, lines, polygons, bitmaps, and images. The technique is to sample all primitives multiple times at each pixel. The color sample values are resolved to a single, displayable color each time a pixel is updated, so the antialiasing appears to be automatic at the application level. Because each sample includes color, depth, and stencil information, the color (including texture operation), depth, and stencil functions perform equivalently to the single-sample mode.

An additional buffer, called the multisample buffer, is added to the framebuffer. Pixel sample values, including color, depth, and stencil values, are stored in this buffer. Samples contain separate color values for each fragment color. When the framebuffer includes a multisample buffer, it does not include depth or stencil buffers, even if the multisample buffer does not store depth or stencil values. Color buffers do coexist with the multisample buffer, however.

Multisample antialiasing is most valuable for rendering polygons, because it requires no sorting for hidden surface elimination, and it correctly handles adjacent polygons, object silhouettes, and even intersecting polygons. If only points or lines are being rendered, the “smooth” antialiasing mechanism provided by the base GL may result in a higher quality image. This mechanism is designed to allow multisample and smooth antialiasing techniques to be alternated during the rendering of a single scene.

If the value of `SAMPLE_BUFFERS` is one, the rasterization of all primitives is changed, and is referred to as multisample rasterization. Otherwise, primitive rasterization is referred to as single-sample rasterization. The value of `SAMPLE_BUFFERS` is queried by calling `GetIntegerv` with `pname` set to `SAMPLE_BUFFERS`.

During multisample rendering the contents of a pixel fragment are changed in two ways. First, each fragment includes a coverage value with `SAMPLES` bits. The value of `SAMPLES` is an implementation-dependent constant, and is queried by calling `GetIntegerv` with `pname` set to `SAMPLES`.

The location of a given sample is queried with the command

```c
void GetMultisamplefv(enum pname, uint index, 
                      float *val);
```

`pname` must be `SAMPLE_POSITION`, and `index` corresponds to the sample for which the location should be returned. The sample location is returned as two floating point values in `val[0]` and `val[1]`, each between 0 and 1, corresponding to the `x` and `y` locations respectively in GL pixel space of that sample. `(0.5, 0.5)` thus corresponds to the pixel center. The error `INVALID_VALUE` is generated if `index` is greater than or equal to the value of `SAMPLES`. If the multisample mode does not
have fixed sample locations, the returned values may only reflect the locations of samples within some pixels.

Second, each fragment includes \texttt{SAMPLES} depth values and sets of associated data, instead of the single depth value and set of associated data that is maintained in single-sample rendering mode. An implementation may choose to assign the same associated data to more than one sample. The location for evaluating such associated data can be anywhere within the pixel including the fragment center or any of the sample locations. The different associated data values need not all be evaluated at the same location. Each pixel fragment thus consists of integer \(x\) and \(y\) grid coordinates, \texttt{SAMPLES} depth values and sets of associated data, and a coverage value with a maximum of \texttt{SAMPLES} bits.

Multisample rasterization is enabled or disabled by calling \texttt{Enable} or \texttt{Disable} with the symbolic constant \texttt{MULTISAMPLE}.

If \texttt{MULTISAMPLE} is disabled, multisample rasterization of all primitives is equivalent to single-sample (fragment-center) rasterization, except that the fragment coverage value is set to full coverage. The color and depth values and the sets of texture coordinates may all be set to the values that would have been assigned by single-sample rasterization, or they may be assigned as described below for multisample rasterization.

If \texttt{MULTISAMPLE} is enabled, multisample rasterization of all primitives differs substantially from single-sample rasterization. It is understood that each pixel in the framebuffer has \texttt{SAMPLES} locations associated with it. These locations are exact positions, rather than regions or areas, and each is referred to as a sample point. The sample points associated with a pixel may be located inside or outside of the unit square that is considered to bound the pixel. Furthermore, the relative locations of sample points may be identical for each pixel in the framebuffer, or they may differ.

If the sample locations differ per pixel, they should be aligned to window, not screen, boundaries. Otherwise rendering results will be window-position specific. The invariance requirement described in section 3.2 is relaxed for all multisample rasterization, because the sample locations may be a function of pixel location.

### 3.4 Points

A point is drawn by generating a set of fragments in the shape of a square or circle centered around the vertex of the point. Each vertex has an associated point size that controls the size of that square or circle.

If no vertex or geometry shader is active, then the rasterization of points is controlled with
3.4. POINTS

```c
void PointSize(float size);
```

`size` specifies the requested size of a point. The default value is 1.0. A value less than or equal to zero results in the error `INVALID_VALUE`.

The requested point size is multiplied with a distance attenuation factor, clamped to a specified point size range, and further clamped to the implementation-dependent point size range to produce the derived point size:

\[
\text{derived size} = \text{clamp} \left( \text{size} \times \sqrt{\left( \frac{1}{a + b \times d + c \times d^2} \right)} \right)
\]

where \(d\) is the eye-coordinate distance from the eye, \((0, 0, 0, 1)\) in eye coordinates, to the vertex, and \(a\), \(b\), and \(c\) are distance attenuation function coefficients.

If multisampling is not enabled, the derived size is passed on to rasterization as the point width.

If a vertex or geometry shader is active and point size mode is enabled, then the derived point size is taken from the (potentially clipped) shader built-in `gl_PointSize` written by the geometry shader, or written by the vertex shader if no geometry shader is active, and clamped to the implementation-dependent point size range. If the value written to `gl_PointSize` is less than or equal to zero, results are undefined. If a vertex and/or geometry shader is active and point size mode is disabled, then the derived point size is taken from the point size state as specified by the `PointSize` command. In this case no distance attenuation is performed.

Program point size mode is enabled and disabled by calling `Enable` or `Disable` with the symbolic value `PROGRAM_POINT_SIZE`.

If multisampling is enabled, an implementation may optionally fade the point alpha (see section 3.14) instead of allowing the point width to go below a given threshold. In this case, the width of the rasterized point is

\[
\text{width} = \begin{cases} 
\text{derived size} & \text{if } \text{derived size} \geq \text{threshold} \\
\text{threshold} & \text{otherwise}
\end{cases}
\] (3.1)

and the fade factor is computed as follows:

\[
\text{fade} = \begin{cases} 
1 & \text{if } \text{derived size} \geq \text{threshold} \\
\left(\frac{\text{derived size}}{\text{threshold}}\right)^2 & \text{otherwise}
\end{cases}
\] (3.2)

The distance attenuation function coefficients \(a\), \(b\), and \(c\), the bounds of the first point size range clamp, and the point fade threshold are specified with

```c
void PointParameter(void (*func)(enum pname, T param));
void PointParameter(void (*func)(enum pname, const T params));
```
3.4. POINTS

If \( \text{pname} \) is \texttt{POINT\_SIZE\_MIN} or \texttt{POINT\_SIZE\_MAX}, then \texttt{param} specifies, or \texttt{params} points to the lower or upper bound respectively to which the derived point size is clamped. If the lower bound is greater than the upper bound, the point size after clamping is undefined. If \( \text{pname} \) is \texttt{POINT\_DISTANCE\_ATTENUATION}, then \texttt{params} points to the coefficients \( a, b, \) and \( c \). If \( \text{pname} \) is \texttt{POINT\_FADE\_THRESHOLD\_SIZE}, then \texttt{param} specifies, or \texttt{params} points to the point fade threshold. Values of \texttt{POINT\_SIZE\_MIN}, \texttt{POINT\_SIZE\_MAX}, or \texttt{POINT\_FADE\_THRESHOLD\_SIZE} less than zero result in the error \texttt{INVALID\_VALUE}.

Point antialiasing is enabled or disabled by calling \texttt{Enable} or \texttt{Disable} with the symbolic constant \texttt{POINT\_SMOOTH}. The default state is for point antialiasing to be disabled.

Point sprites are enabled or disabled by calling \texttt{Enable} or \texttt{Disable} with the symbolic constant \texttt{POINT\_SPRITE}. The default state is for point sprites to be disabled. When point sprites are enabled, the state of the point antialiasing enable is ignored. In a deprecated context, point sprites are always enabled.

The point sprite texture coordinate replacement mode is set with one of the \texttt{TexEnv*} commands described in section 3.9.15, where \texttt{target} is \texttt{POINT\_SPRITE} and \texttt{pname} is \texttt{COORD\_REPLACE}. The possible values for \texttt{param} are \texttt{FALSE} and \texttt{TRUE}. The default value for each texture coordinate set is for point sprite texture coordinate replacement to be disabled.

The point sprite texture coordinate origin is set with the \texttt{PointParameter*} commands where \texttt{pname} is \texttt{POINT\_SPRITE\_COORD\_ORIGIN} and \texttt{param} is \texttt{LOWER\_LEFT} or \texttt{UPPER\_LEFT}. The default value is \texttt{UPPER\_LEFT}.

### 3.4.1 Basic Point Rasterization

In the default state, a point is rasterized by truncating its \( x_w \) and \( y_w \) coordinates (recall that the subscripts indicate that these are \( x \) and \( y \) window coordinates) to integers. This \((x, y)\) address, along with data derived from the data associated with the vertex corresponding to the point, is sent as a single fragment to the per-fragment stage of the GL.

The effect of a point width other than 1.0 depends on the state of point antialiasing and point sprites. If antialiasing and point sprites are disabled, the actual width is determined by rounding the supplied width to the nearest integer, then clamping it to the implementation-dependent maximum non-antialiased point width. This implementation-dependent value must be no less than the implementation-dependent maximum antialiased point width, rounded to the nearest integer value, and in any event no less than 1. If rounding the specified width results in the value
0, then it is as if the value were 1. If the resulting width is odd, then the point

\[(x, y) = \left(\lfloor x_w + \frac{1}{2} \rfloor, \lfloor y_w + \frac{1}{2} \rfloor \right)\]

is computed from the vertex’s \(x_w\) and \(y_w\), and a square grid of the odd width centered at \((x, y)\) defines the centers of the rasterized fragments (recall that fragment centers lie at half-integer window coordinate values). If the width is even, then the center point is

\[(x, y) = \left(\lfloor x_w + \frac{1}{2} \rfloor, \lfloor y_w + \frac{1}{2} \rfloor \right)\];

the rasterized fragment centers are the half-integer window coordinate values within the square of the even width centered on \((x, y)\). See figure 3.2.
Figure 3.3. Rasterization of antialiased wide points. The black dot indicates the point to be rasterized. The shaded region has the specified width. The X marks indicate those fragment centers produced by rasterization. A fragment’s computed coverage value is based on the portion of the shaded region that covers the corresponding fragment square. Solid lines lie on integer coordinates.
3.4. POINTS

All fragments produced in rasterizing a non-antialiased point are assigned the same associated data, which are those of the vertex corresponding to the point.

If antialiasing is enabled and point sprites are disabled, then point rasterization produces a fragment for each fragment square that intersects the region lying within the circle having diameter equal to the current point width and centered at the point’s \( (x_w, y_w) \) (figure 3.3). The coverage value for each fragment is the window coordinate area of the intersection of the circular region with the corresponding fragment square (but see section 3.3). This value is saved and used in the final step of rasterization (section 3.13). The data associated with each fragment are otherwise the data associated with the point being rasterized.

Not all widths need be supported when point antialiasing is on, but the width 1.0 must be provided. If an unsupported width is requested, the nearest supported width is used instead. The range of supported widths and the width of evenly-spaced gradations within that range are implementation-dependent. The range and gradations may be obtained using the query mechanism described in chapter 6. If, for instance, the width range is from 0.1 to 2.0 and the gradation width is 0.1, then the widths 0.1, 0.2, \ldots, 1.9, 2.0 are supported.

If point sprites are enabled, then point rasterization produces a fragment for each framebuffer pixel whose center lies inside a square centered at the point’s \( (x_w, y_w) \), with side length equal to the current point size.

All fragments produced in rasterizing a point sprite are assigned the same associated data, which are those of the vertex corresponding to the point. However, the fragment shader built-in \texttt{gl_PointCoord} contains point sprite texture coordinates. Additionally, for each texture coordinate set where \texttt{COORD_REPLACE} is \texttt{TRUE}, these texture coordinates are replaced with point sprite texture coordinates.

The \( s \) point sprite texture coordinate varies from 0 to 1 across the point horizontally left-to-right. If \texttt{POINT_SPRITE_COORD_ORIGIN} is \texttt{LOWER_LEFT}, the \( t \) coordinate varies from 0 to 1 vertically bottom-to-top. Otherwise if the point sprite texture coordinate origin is \texttt{UPPER_LEFT}, the \( t \) coordinate varies from 0 to 1 vertically top-to-bottom. The \( r \) and \( q \) coordinates are replaced with the constants 0 and 1, respectively.

The following formula is used to evaluate the \( s \) and \( t \) point sprite texture coordinates:

\[
s = \frac{1}{2} + \frac{(x_f + \frac{1}{2} - x_w)}{\text{size}}
\]  

(3.3)
3.4. POINTS

\[ t = \begin{cases} 
\frac{1}{2} + \frac{(y_f + \frac{1}{2} - y_w)}{size}, & \text{POINT_SPRITE_COORD_ORIGIN = LOWER_LEFT} \\
\frac{1}{2} - \frac{(y_f + \frac{1}{2} - y_w)}{size}, & \text{POINT_SPRITE_COORD_ORIGIN = UPPER_LEFT} 
\end{cases} \] 

(3.4)

where \( size \) is the point’s size, \( x_f \) and \( y_f \) are the (integral) window coordinates of the fragment, and \( x_w \) and \( y_w \) are the exact, unrounded window coordinates of the vertex for the point.

The widths supported for point sprites must be a superset of those supported for antialiased points. There is no requirement that these widths must be equally spaced. If an unsupported width is requested, the nearest supported width is used instead.

3.4.2 Point Rasterization State

The state required to control point rasterization consists of the floating-point point width, two floating-point values specifying the minimum and maximum point size, three floating-point values specifying the distance attenuation coefficients, a bit indicating whether or not antialiasing is enabled, a bit indicating whether or not point sprites are enabled, a bit for the point sprite texture coordinate replacement mode for each texture coordinate set, a bit indicating whether or not vertex program point size mode is enabled, a bit for the point sprite texture coordinate origin, and a floating-point value specifying the point fade threshold size.

3.4.3 Point Multisample Rasterization

If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one, then points are rasterized using the following algorithm, regardless of whether point antialiasing (POINT_SMOOTH) is enabled or disabled. Point rasterization produces a fragment for each framebuffer pixel with one or more sample points that intersect a region centered at the point’s \((x_w, y_w)\). This region is a circle having diameter equal to the current point width if POINT_SPRITE is disabled, or a square with side equal to the current point width if POINT_SPRITE is enabled. Coverage bits that correspond to sample points that intersect the region are 1, other coverage bits are 0. All data associated with each sample for the fragment are the data associated with the point being rasterized, with the exception of texture coordinates when POINT_SPRITE is enabled; these texture coordinates are computed as described in section 3.4.

Point size range and number of gradations are equivalent to those supported for antialiased points when POINT_SPRITE is disabled. The set of point sizes sup-
ported is equivalent to those for point sprites without multisample when POINT_SPRITE is enabled.

3.5 Line Segments

A line segment results from a line strip Begin/End object, a line loop, or a series of separate line segments. Line segment rasterization is controlled by several variables. Line width, which may be set by calling

```c
voidLineWidth(float width);
```

with an appropriate positive floating-point width, controls the width of rasterized line segments. The default width is 1.0. Values less than or equal to 0.0 generate the error INVALID_VALUE. Antialiasing is controlled with Enable and Disable using the symbolic constant LINE_SMOOTH. Finally, line segments may be stippled.

Stippling is controlled by a GL command that sets a stipple pattern (see below).

3.5.1 Basic Line Segment Rasterization

Line segment rasterization begins by characterizing the segment as either x-major or y-major. x-major line segments have slope in the closed interval \([-1, 1]\); all other line segments are y-major (slope is determined by the segment’s endpoints). We shall specify rasterization only for x-major segments except in cases where the modifications for y-major segments are not self-evident.

Ideally, the GL uses a “diamond-exit” rule to determine those fragments that are produced by rasterizing a line segment. For each fragment \(f\) with center at window coordinates \((x_f, y_f)\), define a diamond-shaped region that is the intersection of four half planes:

\[
R_f = \{(x, y) \mid |x - x_f| + |y - y_f| < 1/2\}\]

Essentially, a line segment starting at \(p_a\) and ending at \(p_b\) produces those fragments \(f\) for which the segment intersects \(R_f\), except if \(p_b\) is contained in \(R_f\). See figure 3.4.

To avoid difficulties when an endpoint lies on a boundary of \(R_f\) we (in principle) perturb the supplied endpoints by a tiny amount. Let \(p_a\) and \(p_b\) have window coordinates \((x_a, y_a)\) and \((x_b, y_b)\), respectively. Obtain the perturbed endpoints \(p'_a\) given by \((x_a, y_a) - (\epsilon, \epsilon^2)\) and \(p'_b\) given by \((x_b, y_b) - (\epsilon, \epsilon^2)\). Rasterizing the line segment starting at \(p_a\) and ending at \(p'_b\) produces those fragments \(f\) for which the segment starting at \(p'_a\) and ending on \(p'_b\) intersects \(R_f\), except if \(p'_b\) is contained in \(R_f\)
$R_f$. $\epsilon$ is chosen to be so small that rasterizing the line segment produces the same fragments when $\delta$ is substituted for $\epsilon$ for any $0 < \delta \leq \epsilon$.

When $p_a$ and $p_b$ lie on fragment centers, this characterization of fragments reduces to Bresenham’s algorithm with one modification: lines produced in this description are “half-open,” meaning that the final fragment (corresponding to $p_b$) is not drawn. This means that when rasterizing a series of connected line segments, shared endpoints will be produced only once rather than twice (as would occur with Bresenham’s algorithm).

Because the initial and final conditions of the diamond-exit rule may be difficult to implement, other line segment rasterization algorithms are allowed, subject to the following rules:

1. The coordinates of a fragment produced by the algorithm may not deviate by more than one unit in either $x$ or $y$ window coordinates from a corresponding fragment produced by the diamond-exit rule.

2. The total number of fragments produced by the algorithm may differ from that produced by the diamond-exit rule by no more than one.

3. For an $x$-major line, no two fragments may be produced that lie in the same
window-coordinate column (for a $y$-major line, no two fragments may appear in the same row).

4. If two line segments share a common endpoint, and both segments are either $x$-major (both left-to-right or both right-to-left) or $y$-major (both bottom-to-top or both top-to-bottom), then rasterizing both segments may not produce duplicate fragments, nor may any fragments be omitted so as to interrupt continuity of the connected segments.

Next we must specify how the data associated with each rasterized fragment are obtained. Let the window coordinates of a produced fragment center be given by $p_r = (x_d, y_d)$ and let $p_a = (x_a, y_a)$ and $p_b = (x_b, y_b)$. Set

$$t = \frac{(p_r - p_a) \cdot (p_b - p_a)}{\|p_b - p_a\|^2}. \quad (3.5)$$

(Note that $t = 0$ at $p_a$ and $t = 1$ at $p_b$.) The value of an associated datum $f$ for the fragment, whether it be primary or secondary R, G, B, or A (in RGBA mode) or a color index (in color index mode), the fog coordinate, an $s$, $t$, $r$, or $q$ texture coordinate, or the clip $w$ coordinate, is found as

$$f = \frac{(1 - t)f_a/w_a + tf_b/w_b}{(1 - t)/w_a + t/w_b} \quad (3.6)$$

where $f_a$ and $f_b$ are the data associated with the starting and ending endpoints of the segment, respectively; $w_a$ and $w_b$ are the clip $w$ coordinates of the starting and ending endpoints of the segments, respectively. However, depth values for lines must be interpolated by

$$z = (1 - t)z_a + tz_b \quad (3.7)$$

where $z_a$ and $z_b$ are the depth values of the starting and ending endpoints of the segment, respectively.

When using a vertex shader, the noperspective and flat keywords used to declare varying shader outputs affect how they are interpolated. When neither keyword is specified, interpolation is performed as described in equation 3.6. When the noperspective keyword is specified, interpolation is performed in the same fashion as for depth values, as described in equation 3.7. When the flat keyword is specified, no interpolation is performed, and varying outputs are taken from the corresponding varying value of the provoking vertex corresponding to that primitive (see section 2.21).
3.5. LINE SEGMENTS

3.5.2 Other Line Segment Features

We have just described the rasterization of non-antialiased line segments of width one using the default line stipple of $FFFF_{16}$. We now describe the rasterization of line segments for general values of the line segment rasterization parameters.

Line Stipple

The command

```
void LineStipple(int factor, ushort pattern);
```

defines a line stipple. pattern is an unsigned short integer. The line stipple is taken from the lowest order 16 bits of pattern. It determines those fragments that are to be drawn when the line is rasterized. factor is a count that is used to modify the effective line stipple by causing each bit in pattern to be used factor times. factor is clamped to the range $[1, 256]$. Line stippling may be enabled or disabled using Enable or Disable with the constant LINE_STIPPLE. When disabled, it is as if the line stipple has its default value.

Line stippling masks certain fragments that are produced by rasterization so that they are not sent to the per-fragment stage of the GL. The masking is achieved using three parameters: the 16-bit line stipple $p$, the line repeat count $r$, and an integer stipple counter $s$. Let

$$b = \lfloor s/r \rfloor \mod 16,$$

Then a fragment is produced if the $b$th bit of $p$ is 1, and not produced otherwise. The bits of $p$ are numbered with 0 being the least significant and 15 being the most significant. The initial value of $s$ is zero; $s$ is incremented after production of each fragment of a line segment (fragments are produced in order, beginning at the starting point and working towards the ending point). $s$ is reset to 0 whenever a Begin occurs, and before every line segment in a group of independent segments (as specified when Begin is invoked with LINES).

If the line segment has been clipped, then the value of $s$ at the beginning of the line segment is indeterminate.

Wide Lines

The actual width of non-antialiased lines is determined by rounding the supplied width to the nearest integer, then clamping it to the implementation-dependent maximum non-antialiased line width. This implementation-dependent value must be no less than the implementation-dependent maximum antialiased line width,
rounded to the nearest integer value, and in any event no less than 1. If rounding the specified width results in the value 0, then it is as if the value were 1.

Non-antialiased line segments of width other than one are rasterized by offsetting them in the minor direction (for an x-major line, the minor direction is y, and for a y-major line, the minor direction is x) and replicating fragments in the minor direction (see figure 3.5). Let \( w \) be the width rounded to the nearest integer (if \( w = 0 \), then it is as if \( w = 1 \)). If the line segment has endpoints given by \((x_0, y_0)\) and \((x_1, y_1)\) in window coordinates, the segment with endpoints \((x_0, y_0 - (w - 1)/2)\) and \((x_1, y_1 - (w - 1)/2)\) is rasterized, but instead of a single fragment, a column of fragments of height \( w \) (a row of fragments of length \( w \) for a y-major segment) is produced at each \( x \) (y for y-major) location. The lowest fragment of this column is the fragment that would be produced by rasterizing the segment of width 1 with the modified coordinates. The whole column is not produced if the stipple bit for the column’s \( x \) location is zero; otherwise, the whole column is produced.
Antialiasing

Rasterized antialiased line segments produce fragments whose fragment squares intersect a rectangle centered on the line segment. Two of the edges are parallel to the specified line segment; each is at a distance of one-half the current width from that segment: one above the segment and one below it. The other two edges pass through the line endpoints and are perpendicular to the direction of the specified line segment. Coverage values are computed for each fragment by computing the area of the intersection of the rectangle with the fragment square (see figure 3.6; see also section 3.3). Equation 3.6 is used to compute associated data values just as with non-antialiased lines; equation 3.5 is used to find the value of $t$ for each fragment whose square is intersected by the line segment’s rectangle. Not all widths need be supported for line segment antialiasing, but width 1.0 antialiased segments must be provided. As with the point width, a GL implementation may be queried for the range and number of gradations of available antialiased line widths.

For purposes of antialiasing, a stippled line is considered to be a sequence of contiguous rectangles centered on the line segment. Each rectangle has width equal to the current line width and length equal to 1 pixel (except the last, which may be shorter). These rectangles are numbered from 0 to $n$, starting with the rectangle incident on the starting endpoint of the segment. Each of these rectangles is either eliminated or produced according to the procedure given under Line Stipple, above, where “fragment” is replaced with “rectangle.” Each rectangle so produced
3.6. POLYGONS

A polygon results from a triangle arising from a triangle strip, triangle fan, or series of separate triangles, a polygon Begin/End object, or a quadrilateral arising from a
quadrilateral strip, series of separate quadrilaterals, or Rect command. Like points and line segments, polygon rasterization is controlled by several variables. Polygon antialiasing is controlled with Enable and Disable with the symbolic constant POLYGON_SMOOTH. The analog to line segment stippling for polygons is polygon stippling, described below.

### 3.6.1 Basic Polygon Rasterization

The first step of polygon rasterization is to determine if the polygon is back-facing or front-facing. This determination is made based on the sign of the (clipped or unclipped) polygon’s area computed in window coordinates. One way to compute this area is

\[
a = \frac{1}{2} \sum_{i=0}^{n-1} x_i^w y_{i+1}^w - x_{i+1}^w y_i^w \tag{3.8}
\]

where \(x_i^w\) and \(y_i^w\) are the \(x\) and \(y\) window coordinates of the \(i\)th vertex of the \(n\)-vertex polygon (vertices are numbered starting at zero for purposes of this computation) and \(i \oplus 1\) is \((i + 1) \mod n\). The interpretation of the sign of this value is controlled with

```c
void FrontFace( enum dir );
```

Setting \(dir\) to CCW (corresponding to counter-clockwise orientation of the projected polygon in window coordinates) uses \(a\) as computed above. Setting \(dir\) to CW (corresponding to clockwise orientation) indicates that the sign of \(a\) should be reversed prior to use. Front face determination requires one bit of state, and is initially set to CCW.

If the sign of \(a\) (including the possible reversal of this sign as determined by FrontFace) is positive, the polygon is front-facing; otherwise, it is back-facing. This determination is used in conjunction with the CullFace enable bit and mode value to decide whether or not a particular polygon is rasterized. The CullFace mode is set by calling

```c
void CullFace( enum mode );
```

\(mode\) is a symbolic constant: one of FRONT, BACK or FRONT_AND_BACK. Culling is enabled or disabled with Enable or Disable using the symbolic constant CULL_FACE. Front-facing polygons are rasterized if either culling is disabled or the CullFace mode is BACK while back-facing polygons are rasterized only if either culling
is disabled or the **CullFace** mode is **FRONT**. The initial setting of the **CullFace** mode is **BACK**. Initially, culling is disabled.

The rule for determining which fragments are produced by polygon rasterization is called **point sampling**. The two-dimensional projection obtained by taking the \(x\) and \(y\) window coordinates of the polygon’s vertices is formed. Fragment centers that lie inside of this polygon are produced by rasterization. Special treatment is given to a fragment whose center lies on a polygon boundary edge. In such a case we require that if two polygons lie on either side of a common edge (with identical endpoints) on which a fragment center lies, then exactly one of the polygons results in the production of the fragment during rasterization.

As for the data associated with each fragment produced by rasterizing a polygon, we begin by specifying how these values are produced for fragments in a triangle. Define **barycentric coordinates** for a triangle. Barycentric coordinates are a set of three numbers, \(a\), \(b\), and \(c\), each in the range \([0, 1]\), with \(a + b + c = 1\). These coordinates uniquely specify any point \(p\) within the triangle or on the triangle’s boundary as

\[
p = ap_a + bp_b + cp_c,
\]

where \(p_a\), \(p_b\), and \(p_c\) are the vertices of the triangle. \(a\), \(b\), and \(c\) can be found as

\[
a = \frac{A(pbp_c)}{A(p_apbp_c)}, \quad b = \frac{A(pp_ap_c)}{A(p_apbp_c)}, \quad c = \frac{A(pp_apb)}{A(p_apbp_c)},
\]

where \(A(lmn)\) denotes the area in window coordinates of the triangle with vertices \(l\), \(m\), and \(n\).

Denote an associated datum at \(p_a\), \(p_b\), or \(p_c\) as \(f_a\), \(f_b\), or \(f_c\), respectively. Then the value \(f\) of a datum at a fragment produced by rasterizing a triangle is given by

\[
f = \frac{af_a/w_a + bf_b/w_b + cf_c/w_c}{a/w_a + b/w_b + c/w_c}
\]  \hspace{1cm} (3.9)

where \(w_a\), \(w_b\) and \(w_c\) are the clip \(w\) coordinates of \(p_a\), \(p_b\), and \(p_c\), respectively. \(a\), \(b\), and \(c\) are the barycentric coordinates of the fragment for which the data are produced. \(a\), \(b\), and \(c\) must correspond precisely to the exact coordinates of the center of the fragment. Another way of saying this is that the data associated with a fragment must be sampled at the fragment’s center. However, depth values for polygons must be interpolated by

\[
z = az_a + bz_b + cz_c
\]  \hspace{1cm} (3.10)

where \(z_a\), \(z_b\), and \(z_c\) are the depth values of \(p_a\), \(p_b\), and \(p_c\), respectively.

When using a vertex shader, the **noperspective** and **flat** keywords used to declare varying shader outputs affect how they are interpolated. When neither
3.6. POLYGONS

When the noperspective keyword is specified, interpolation is performed in the same fashion as for depth values, as described in equation 3.10. When the flat keyword is specified, no interpolation is performed, and varying outputs are taken from the corresponding varying value of the provoking vertex corresponding to that primitive (see section 2.21).

For a polygon with more than three edges, we require only that a convex combination of the values of the datum at the polygon’s vertices can be used to obtain the value assigned to each fragment produced by the rasterization algorithm. That is, it must be the case that at every fragment

\[ f = \sum_{i=1}^{n} a_i f_i \]

where \( n \) is the number of vertices in the polygon, \( f_i \) is the value of the \( f \) at vertex \( i \); for each \( i \), \( 0 \leq a_i \leq 1 \) and \( \sum_{i=1}^{n} a_i = 1 \). The values of the \( a_i \) may differ from fragment to fragment, but at vertex \( i \), \( a_j = 0 \), \( j \neq i \) and \( a_i = 1 \).

One algorithm that achieves the required behavior is to triangulate a polygon (without adding any vertices) and then treat each triangle individually as already discussed. A scan-line rasterizer that linearly interpolates data along each edge and then linearly interpolates data across each horizontal span from edge to edge also satisfies the restrictions (in this case, the numerator and denominator of equation 3.9 should be iterated independently and a division performed for each fragment).

3.6.2 Stippling

Polygon stippling works much the same way as line stippling, masking out certain fragments produced by rasterization so that they are not sent to the next stage of the GL. This is the case regardless of the state of polygon antialiasing. Stippling is controlled with

```c
void PolygonStipple(ubyte *pattern);
```

`pattern` is a pointer to memory into which a \( 32 \times 32 \) pattern is packed. The pattern is unpacked from memory according to the procedure given in section 3.7.5 for `DrawPixels`; it is as if the `height` and `width` passed to that command were both equal to 32, the `type` were `BITMAP`, and the `format` were `COLOR_INDEX`. The unpacked values (before any conversion or arithmetic would have been performed) form a stipple pattern of zeros and ones.
If \( x_w \) and \( y_w \) are the window coordinates of a rasterized polygon fragment, then that fragment is sent to the next stage of the GL if and only if the bit of the pattern \((x_w \mod 32, y_w \mod 32)\) is 1.

Polygon stippling may be enabled or disabled with \texttt{Enable} or \texttt{Disable} using the constant \texttt{POLYGON_STIPPLE}. When disabled, it is as if the stipple pattern were all ones.

### 3.6.3 Antialiasing

Polygon antialiasing rasterizes a polygon by producing a fragment wherever the interior of the polygon intersects that fragment’s square. A coverage value is computed at each such fragment, and this value is saved to be applied as described in section 3.13. An associated datum is assigned to a fragment by integrating the datum’s value over the region of the intersection of the fragment square with the polygon’s interior and dividing this integrated value by the area of the intersection. For a fragment square lying entirely within the polygon, the value of a datum at the fragment’s center may be used instead of integrating the value across the fragment.

Polygon stippling operates in the same way whether polygon antialiasing is enabled or not. The polygon point sampling rule defined in section 3.6.1, however, is not enforced for antialiased polygons.

### 3.6.4 Options Controlling Polygon Rasterization

The interpretation of polygons for rasterization is controlled using

\[
\texttt{void \ PolygonMode( enum face, enum mode );}
\]

\texttt{face} is one of \texttt{FRONT}, \texttt{BACK}, or \texttt{FRONT_AND_BACK}, indicating that the rasterizing method described by \texttt{mode} respectively replaces the rasterizing method for front-facing polygons, back-facing polygons, or both front- and back-facing polygons. \texttt{mode} is one of the symbolic constants \texttt{POINT}, \texttt{LINE}, or \texttt{FILL}. Calling \texttt{PolygonMode} with \texttt{POINT} causes certain vertices of a polygon to be treated, for rasterization purposes, just as if they were enclosed within a \texttt{Begin(POINTS)} and \texttt{End} pair. The vertices selected for this treatment are those that have been tagged as having a polygon boundary edge beginning on them (see section 2.6.2). \texttt{LINE} causes edges that are tagged as boundary to be rasterized as line segments. (The line stipple counter is reset at the beginning of the first rasterized edge of the polygon, but not for subsequent edges.) \texttt{FILL} is the default mode of polygon rasterization, corresponding to the description in sections 3.6.1, 3.6.2, and 3.6.3. Note that these
modes affect only the final rasterization of polygons: in particular, a polygon’s vertices are lit, and the polygon is clipped and possibly culled before these modes are applied.

Polygon antialiasing applies only to the \texttt{FILL} state of \texttt{PolygonMode}. For \texttt{POINT} or \texttt{LINE}, point antialiasing or line segment antialiasing, respectively, apply.

### 3.6.5 Depth Offset

The depth values of all fragments generated by the rasterization of a polygon may be offset by a single value that is computed for that polygon. The function that determines this value is specified by calling

```c
void PolygonOffset(float factor, float units);
```

\( \text{factor} \) scales the maximum depth slope of the polygon, and \( \text{units} \) scales an implementation-dependent constant that relates to the usable resolution of the depth buffer. The resulting values are summed to produce the polygon offset value. Both \( \text{factor} \) and \( \text{units} \) may be either positive or negative.

The maximum depth slope \( m \) of a triangle is

\[
m = \sqrt{\left(\frac{\partial z_w}{\partial x_w}\right)^2 + \left(\frac{\partial z_w}{\partial y_w}\right)^2} \tag{3.11}
\]

where \((x_w, y_w, z_w)\) is a point on the triangle. \( m \) may be approximated as

\[
m = \max \left\{ \left| \frac{\partial z_w}{\partial x_w} \right|, \left| \frac{\partial z_w}{\partial y_w} \right| \right\}. \tag{3.12}
\]

If the polygon has more than three vertices, one or more values of \( m \) may be used during rasterization. Each may take any value in the range \([\min, \max]\), where \( \min \) and \( \max \) are the smallest and largest values obtained by evaluating equation 3.11 or equation 3.12 for the triangles formed by all three-vertex combinations.

The minimum resolvable difference \( r \) is an implementation-dependent parameter that depends on the depth buffer representation. It is the smallest difference in window coordinate \( z \) values that is guaranteed to remain distinct throughout polygon rasterization and in the depth buffer. All pairs of fragments generated by the rasterization of two polygons with otherwise identical vertices, but \( z_w \) values that differ by \( r \), will have distinct depth values.

For fixed-point depth buffer representations, \( r \) is constant throughout the range of the entire depth buffer. For floating-point depth buffers, there is no single minimum resolvable difference. In this case, the minimum resolvable difference for a
given polygon is dependent on the maximum exponent, \( e \), in the range of \( z \) values spanned by the primitive. If \( n \) is the number of bits in the floating-point mantissa, the minimum resolvable difference, \( r \), for the given primitive is defined as

\[
r = 2^{e-n}.
\]

The offset value \( o \) for a polygon is

\[
o = m \times \text{factor} + r \times \text{units}.
\]  

(3.13)

\( m \) is computed as described above. If the depth buffer uses a fixed-point representation, \( m \) is a function of depth values in the range \([0, 1]\), and \( o \) is applied to depth values in the same range.

Boolean state values \texttt{POLYGON_OFFSET_POINT}, \texttt{POLYGON_OFFSET_LINE}, and \texttt{POLYGON_OFFSET_FILL} determine whether \( o \) is applied during the rasterization of polygons in \texttt{POINT}, \texttt{LINE}, and \texttt{FILL} modes. These boolean state values are enabled and disabled as argument values to the commands \texttt{Enable} and \texttt{Disable}. If \texttt{POLYGON_OFFSET_POINT} is enabled, \( o \) is added to the depth value of each fragment produced by the rasterization of a polygon in \texttt{POINT} mode. Likewise, if \texttt{POLYGON_OFFSET_LINE} or \texttt{POLYGON_OFFSET_FILL} is enabled, \( o \) is added to the depth value of each fragment produced by the rasterization of a polygon in \texttt{LINE} or \texttt{FILL} modes, respectively.

For fixed-point depth buffers, fragment depth values are always limited to the range \([0, 1]\), either by clamping after offset addition is performed (preferred), or by clamping the vertex values used in the rasterization of the polygon. Fragment depth values are clamped even when the depth buffer uses a floating-point representation.

### 3.6.6 Polygon Multisample Rasterization

If \texttt{MULTISAMPLE} is enabled and the value of \texttt{SAMPLE_BUFFERS} is one, then polygons are rasterized using the following algorithm, regardless of whether polygon antialiasing (\texttt{POLYGON_SMOOTH}) is enabled or disabled. Polygon rasterization produces a fragment for each framebuffer pixel with one or more sample points that satisfy the point sampling criteria described in section 3.6.1, including the special treatment for sample points that lie on a polygon boundary edge. If a polygon is culled, based on its orientation and the \texttt{CullFace} mode, then no fragments are produced during rasterization. Fragments are culled by the polygon stipple just as they are for aliased and antialiased polygons.

Coverage bits that correspond to sample points that satisfy the point sampling criteria are 1, other coverage bits are 0. Each associated datum is produced as described in section 3.6.1, but using the corresponding sample location instead of
the fragment center. An implementation may choose to assign the same associated data values to more than one sample by barycentric evaluation using any location within the pixel including the fragment center or one of the sample locations. The color value and the set of texture coordinates need not be evaluated at the same location.

When using a vertex shader, the `noperspective` and `flat` qualifiers affect how varying shader outputs are interpolated in the same fashion as described for basic polygon rasterization in section 3.6.1.

The rasterization described above applies only to the `FILL` state of `Polygon-Mode`. For `POINT` and `LINE`, the rasterizations described in sections 3.4.3 (Point Multisample Rasterization) and 3.5.4 (Line Multisample Rasterization) apply.

### 3.6.7 Polygon Rasterization State

The state required for polygon rasterization consists of a polygon stipple pattern, whether stippling is enabled or disabled, the current state of polygon antialiasing (enabled or disabled), the current values of the `PolygonMode` setting for each of front- and back-facing polygons, whether point, line, and fill mode polygon offsets are enabled or disabled, and the factor and bias values of the polygon offset equation. The initial stipple pattern is all ones; initially stippling is disabled. The initial setting of polygon antialiasing is disabled. The initial state for `PolygonMode` is `FILL` for both front- and back-facing polygons. The initial polygon offset factor and bias values are both 0; initially polygon offset is disabled for all modes.

### 3.7 Pixel Rectangles

Rectangles of color, depth, and certain other values may be specified to the GL using `TexImage*D` (see section 3.9.1) or converted to fragments using the `Draw-Pixels` command (described in section 3.7.5). Some of the parameters and operations governing the operation of these commands are shared by `CopyPixels` (used to copy pixels from one framebuffer location to another) and `ReadPixels` (used to obtain pixel values from the framebuffer); the discussion of `CopyPixels` and `ReadPixels`, however, is deferred until chapter 4 after the framebuffer has been discussed in detail. Nevertheless, we note in this section when parameters and state pertaining to these commands also pertain to `CopyPixels` or `ReadPixels`.

A number of parameters control the encoding of pixels in buffer object or client memory (for reading and writing) and how pixels are processed before being placed in or after being read from the framebuffer (for reading, writing, and copying). These parameters are set with three commands: `PixelStore`, `PixelTransfer`, and

Table 3.1: **PixelStore** parameters pertaining to one or more of **DrawPixels**, **ColorTable**, **ColorSubTable**, **ConvolutionFilter1D**, **ConvolutionFilter2D**, **SeparableFilter2D**, **PolygonStipple**, **TexImage1D**, **TexImage2D**, **TexImage3D**, **TexSubImage1D**, **TexSubImage2D**, and **TexSubImage3D**.

#### 3.7.1 Pixel Storage Modes and Pixel Buffer Objects

Pixel storage modes affect the operation of **TexImage*D**, **TexSubImage*D**, **DrawPixels**, and **ReadPixels** (as well as other commands; see sections 3.6.2 and 3.8) when one of these commands is issued. This may differ from the time that the command is executed if the command is placed in a display list (see section 5.4). Pixel storage modes are set with

```c
void PixelStore{if}({enum pname, T param});
```

pname is a symbolic constant indicating a parameter to be set, and param is the value to set it to. Table 3.1 summarizes the pixel storage parameters, their types, their initial values, and their allowable ranges. Setting a parameter to a value outside the given range results in the error **INVALID_VALUE**.

The version of **PixelStore** that takes a floating-point value may be used to set any type of parameter; if the parameter is boolean, then it is set to **FALSE** if the passed value is 0.0 and **TRUE** otherwise, while if the parameter is an integer, then the passed value is rounded to the nearest integer. The integer version of the command may also be used to set any type of parameter; if the parameter is boolean, then it is set to **FALSE** if the passed value is 0 and **TRUE** otherwise, while if the parameter is a floating-point value, then the passed value is converted to floating-point.
3.7. PIXEL RECTANGLES

In addition to storing pixel data in client memory, pixel data may also be stored in buffer objects (described in section 2.9). The current pixel unpack and pack buffer objects are designated by the PIXEL_UNPACK_BUFFER and PIXEL_PACK_BUFFER targets respectively.

Initially, zero is bound for the PIXEL_UNPACK_BUFFER, indicating that image specification commands such as DrawPixels source their pixels from client memory pointer parameters. However, if a non-zero buffer object is bound as the current pixel unpack buffer, then the pointer parameter is treated as an offset into the designated buffer object.

3.7.2 The Imaging Subset

Some pixel transfer and per-fragment operations are only made available in GL implementations which incorporate the optional imaging subset. The imaging subset includes both new commands, and new enumerants allowed as parameters to existing commands. If the subset is supported, all of these calls and enumerants must be implemented as described later in the GL specification. If the subset is not supported, calling any unsupported command generates the error INVALID_OPERATION, and using any of the new enumerants generates the error INVALID_ENUM.

The individual operations available only in the imaging subset are described in section 3.7.3. Imaging subset operations include:

1. Color tables, including all commands and enumerants described in subsections Color Table Specification, Alternate Color Table Specification Commands, Color Table State and Proxy State, Color Table Lookup, Post Convolution Color Table Lookup, and Post Color Matrix Color Table Lookup, as well as the query commands described in section 6.1.7.

2. Convolution, including all commands and enumerants described in subsections Convolution Filter Specification, Alternate Convolution Filter Specification Commands, and Convolution, as well as the query commands described in section 6.1.8.

3. Color matrix, including all commands and enumerants described in subsections Color Matrix Specification and Color Matrix Transformation, as well as the simple query commands described in section 6.1.6.

4. Histogram and minmax, including all commands and enumerants described in subsections Histogram Table Specification, Histogram State and Proxy State, Histogram, Minmax Table Specification, and Minmax, as well as the query commands described in section 6.1.9 and section 6.1.10.

Table 3.2: `PixelTransfer` parameters. *x* is RED, GREEN, BLUE, or ALPHA.

The imaging subset is supported only if the `EXTENSIONS` string includes the substring "GL_ARB_imaging" Querying `EXTENSIONS` is described in section 6.1.4.

If the imaging subset is not supported, the related pixel transfer operations are not performed; pixels are passed unchanged to the next operation.

#### 3.7.3 Pixel Transfer Modes

Pixel transfer modes affect the operation of `DrawPixels` (section 3.7.5), `ReadPixels` (section 4.3.2), and `CopyPixels` (section 4.3.3) at the time when one of these commands is executed (which may differ from the time the command is issued). Some pixel transfer modes are set with

```c
void PixelTransfer{if}( enum param, T value );
```

`param` is a symbolic constant indicating a parameter to be set, and `value` is the value to set it to. Table 3.2 summarizes the pixel transfer parameters that are set with `PixelTransfer`, their types, their initial values, and their allowable ranges. Setting a parameter to a value outside the given range results in the error `INVALID_ VALUE`. The same versions of the command exist as for `PixelStore`, and the same rules apply to accepting and converting passed values to set parameters.

The pixel map lookup tables are set with

```c
void PixelMap{ui us f}v( enum map, sizei size, T values );
```
### 3.7. PIXEL RECTANGLES

</tr>
</tbody>
</table>

Table 3.3: **PixelMap** parameters.

*map* is a symbolic map name, indicating the map to set, *size* indicates the size of the map, and *values* refers to an array of *size* map values.

The entries of a table may be specified using one of three types: single-precision floating-point, unsigned short integer, or unsigned integer, depending on which of the three versions of **PixelMap** is called. A table entry is converted to the appropriate type when it is specified. An entry giving a color component value is converted as described in equation 2.1 and then clamped to the range $[0, 1]$. An entry giving a color index value is converted from an unsigned short integer or unsigned integer to floating-point. An entry giving a stencil index is converted from single-precision floating-point to an integer by rounding to nearest. The various tables and their initial sizes and entries are summarized in table 3.3. A table that takes an index as an address must have *size* = $2^n$ or the error **INVALID_VALUE** results. The maximum allowable *size* of each table is specified by the implementation-dependent value **MAX_PIXEL_MAP_TABLE**, but must be at least 32 (a single maximum applies to all tables). The error **INVALID_VALUE** is generated if a *size* larger than the implemented maximum, or less than one, is given to **PixelMap**.

If a pixel unpack buffer is bound (as indicated by a non-zero value of **PIXEL_UNPACK_BUFFER_BINDING**), *values* is an offset into the pixel unpack buffer; otherwise, *values* is a pointer to client memory. All pixel storage and pixel transfer modes are ignored when specifying a pixel map. *n* machine units are read where *n* is the *size* of the pixel map times the size of a float, uint, or ushort datum in basic machine units, depending on the respective **PixelMap** version. If a pixel unpack buffer object is bound and *data + n* is greater than the size of the pixel buffer, an **INVALID_OPERATION** error results. If a pixel unpack buffer object is bound
Table 3.4: Color table names. Regular tables have associated image data. Proxy tables have no image data, and are used only to determine if an image can be loaded into the corresponding regular table.

</tbody>
</table>

and values is not evenly divisible by the number of basic machine units needed to store in memory a float, uint, or ushort datum depending on their respective PixelMap version, an INVALID_OPERATION error results.

Color Table Specification

Color lookup tables are specified with

```c
void ColorTable( enum target, enum internalformat,
sizei width, enum format, enum type, void *data );
```

target must be one of the regular color table names listed in table 3.4 to define the table. A proxy table name is a special case discussed later in this section. width, format, type, and data specify an image in memory with the same meaning and allowed values as the corresponding arguments to DrawPixels (see section 3.7.5), with height taken to be 1. The maximum allowable width of a table is implementation-dependent, but must be at least 32. The formats COLOR_-INDEX, DEPTH_COMPONENT, DEPTH_STENCIL, and STENCIL_INDEX and the type BITMAP are not allowed.

The specified image is taken from memory and processed just as if DrawPixels were called, stopping after the final expansion to RGBA. The R, G, B, and A components of each pixel are then scaled by the four COLOR_TABLE_SCALE parameters and biased by the four COLOR_TABLE_BIAS parameters. These parameters are set by calling ColorTableParameterfv as described below. If fragment color clamping is enabled or internalformat is fixed-point, components are clamped to [0, 1]. Otherwise, components are not modified.
Components are then selected from the resulting R, G, B, and A values to obtain a table with the base internal format specified by (or derived from) \( \text{internalformat} \), in the same manner as for textures (section 3.9.1). \( \text{internalformat} \) must be one of the formats in table 3.16 or tables 3.17 - 3.19, with the exception of the RED, RG, DEPTH_COMPONENT, and DEPTH_STENCIL base and sized internal formats in those tables, all sized internal formats with non-fixed internal data types (see section 3.9), and sized internal format RGB9_E5.

The color lookup table is redefined to have \( \text{width} \) entries, each with the specified internal format. The table is formed with indices 0 through \( \text{width} - 1 \). Table location \( i \) is specified by the \( i \)th image pixel, counting from zero.

The error INVALID_VALUE is generated if \( \text{width} \) is not zero or a non-negative power of two. The error TABLE_TOO_LARGE is generated if the specified color lookup table is too large for the implementation.

The scale and bias parameters for a table are specified by calling

\[
\text{void ColorTableParameter}\{\text{if}\}v(\text{enum target, enum pname, T params});
\]

\( \text{target} \) must be a regular color table name. \( \text{pname} \) is one of COLOR_TABLE_SCALE or COLOR_TABLE_BIAS. \( \text{params} \) points to an array of four values: red, green, blue, and alpha, in that order.

A GL implementation may vary its allocation of internal component resolution based on any ColorTable parameter, but the allocation must not be a function of any other factor, and cannot be changed once it is established. Allocations must be invariant; the same allocation must be made each time a color table is specified with the same parameter values. These allocation rules also apply to proxy color tables, which are described later in this section.

Alternate Color Table Specification Commands

Color tables may also be specified using image data taken directly from the framebuffer, and portions of existing tables may be respecified.

The command

\[
\text{void CopyColorTable}(\text{enum target, enum internalformat, int x, int y, sizei width});
\]

defines a color table in exactly the manner of ColorTable, except that table data are taken from the framebuffer, rather than from client memory. \( \text{target} \) must be a regular color table name. \( x, y, \) and \( \text{width} \) correspond precisely to the corresponding arguments of CopyPixels (refer to section 4.3.3); they specify the image’s \( \text{width} \).
and the lower left \((x, y)\) coordinates of the framebuffer region to be copied. The image is taken from the framebuffer exactly as if these arguments were passed to \texttt{CopyPixels} with argument \texttt{type} set to \texttt{COLOR} and \texttt{height} set to 1, stopping after the final expansion to RGBA.

Subsequent processing is identical to that described for \texttt{ColorTable}, beginning with scaling by \texttt{COLOR\_TABLE\_SCALE}. Parameters \texttt{target}, \texttt{internalformat} and \texttt{width} are specified using the same values, with the same meanings, as the equivalent arguments of \texttt{ColorTable}. \texttt{format} is taken to be \texttt{RGBA}.

Two additional commands,

\begin{verbatim}
void ColorSubTable( enum target, sizei start, sizei count,
                  enum format, enum type, void *data );
void CopyColorSubTable( enum target, sizei start, int x,
                        int y, sizei count );
\end{verbatim}

respecify only a portion of an existing color table. No change is made to the \texttt{internalformat} or \texttt{width} parameters of the specified color table, nor is any change made to table entries outside the specified portion. \texttt{target} must be a regular color table name.

\texttt{ColorSubTable} arguments \texttt{format}, \texttt{type}, and \texttt{data} match the corresponding arguments to \texttt{ColorTable}, meaning that they are specified using the same values, and have the same meanings. Likewise, \texttt{CopyColorSubTable} arguments \texttt{x}, \texttt{y}, and \texttt{count} match the \texttt{x}, \texttt{y}, and \texttt{width} arguments of \texttt{CopyColorTable}. Both of the \texttt{ColorSubTable} commands interpret and process pixel groups in exactly the manner of their \texttt{ColorTable} counterparts, except that the assignment of R, G, B, and A pixel group values to the color table components is controlled by the \texttt{internalformat} of the table, not by an argument to the command.

Arguments \texttt{start} and \texttt{count} of \texttt{ColorSubTable} and \texttt{CopyColorSubTable} specify a subregion of the color table starting at index \texttt{start} and ending at index \texttt{start} + \texttt{count} − 1. Counting from zero, the \(n\)th pixel group is assigned to the table entry with index \texttt{count} + \(n\). The error \texttt{INVALID\_VALUE} is generated if \texttt{start} + \texttt{count} > \texttt{width}.

Calling \texttt{CopyColorTable} or \texttt{CopyColorSubTable} will result in an \texttt{INVALID\_FRAMEBUFFER\_OPERATION} error if the object bound to \texttt{READ\_FRAMEBUFFER\_BINDING} is not framebuffer complete (see section 4.4.4).

Color Table State and Proxy State

The state necessary for color tables can be divided into two categories. For each of the three tables, there is an array of values. Each array has associated with it
a width, an integer describing the internal format of the table, six integer values describing the resolutions of each of the red, green, blue, alpha, luminance, and intensity components of the table, and two groups of four floating-point numbers to store the table scale and bias. Each initial array is null (zero width, internal format RGBA, with zero-sized components). The initial value of the scale parameters is (1,1,1,1) and the initial value of the bias parameters is (0,0,0,0).

In addition to the color lookup tables, partially instantiated proxy color lookup tables are maintained. Each proxy table includes width and internal format state values, as well as state for the red, green, blue, alpha, luminance, and intensity component resolutions. Proxy tables do not include image data, nor do they include scale and bias parameters. When `ColorTable` is executed with `target` specified as one of the proxy color table names listed in table 3.4, the proxy state values of the table are recomputed and updated. If the table is too large, no error is generated, but the proxy format, width and component resolutions are set to zero. If the color table would be accommodated by `ColorTable` called with `target` set to the corresponding regular table name (COLOR_TABLE is the regular name corresponding to PROXY_-COLOR_TABLE, for example), the proxy state values are set exactly as though the regular table were being specified. Calling `ColorTable` with a proxy `target` has no effect on the image or state of any actual color table.

There is no image associated with any of the proxy targets. They cannot be used as color tables, and they must never be queried using `GetColorTable`. The error INVALID_ENUM is generated if this is attempted.

### Convolution Filter Specification

A two-dimensional convolution filter image is specified by calling

```c
void ConvolutionFilter2D(enum target, enum internalformat,
                       sizei width,sizei height, enum format, enum type,
                        void *data);
```

`target` must be CONVOLUTION_2D. `width`, `height`, `format`, `type`, and `data` specify an image in memory with the same meaning and allowed values as the corresponding parameters to `DrawPixels`. The formats COLOR_INDEX, DEPTH_COMPONENT, DEPTH_STENCIL, and STENCIL_INDEX and the type BITMAP are not allowed.

The specified image is extracted from memory and processed just as if `DrawPixels` were called, stopping after the final expansion to RGBA. The R, G, B, and A components of each pixel are then scaled by the four two-dimensional CONVOLUTION_FILTER_SCALE parameters and biased by the four two-dimensional CONVOLUTION_FILTER_BIAS parameters. These parameters...
are set by calling ConvolutionParameterfv as described below. No clamping takes place at any time during this process.

Components are then selected from the resulting R, G, B, and A values to obtain a table with the base internal format specified by (or derived from) internalformat, in the same manner as for textures (section 3.9.1). internalformat accepts the same values as the corresponding argument of ColorTable.

The red, green, blue, alpha, luminance, and/or intensity components of the pixels are stored in floating point, rather than integer format. They form a two-dimensional image indexed with coordinates i, j such that i increases from left to right, starting at zero, and j increases from bottom to top, also starting at zero. Image location i, j is specified by the Nth pixel, counting from zero, where

\[ N = i + j \times width \]

The error INVALID_VALUE is generated if width or height is greater than the maximum supported value. These values are queried with GetConvolutionParameteriv, setting target to CONVOLUTION_2D and pname to MAX_CONVOLUTION_WIDTH or MAX_CONVOLUTION_HEIGHT, respectively.

The scale and bias parameters for a two-dimensional filter are specified by calling

```c
void ConvolutionParameterfv( enum target, enum pname,
    T params );
```

with target CONVOLUTION_2D. pname is one of CONVOLUTION_FILTER_SCALE or CONVOLUTION_FILTER_BIAS. params points to an array of four values: red, green, blue, and alpha, in that order.

A one-dimensional convolution filter is defined using

```c
void ConvolutionFilter1D( enum target, enum internalformat,
    size width, enum format, enum type, void *data );
```

target must be CONVOLUTION_1D. internalformat, width, format, and type have identical semantics and accept the same values as do their two-dimensional counterparts. data must point to a one-dimensional image, however.

The image is extracted from memory and processed as if ConvolutionFilter2D were called with a height of 1, except that it is scaled and biased by the one-dimensional CONVOLUTION_FILTER_SCALE and CONVOLUTION_FILTER_BIAS parameters. These parameters are specified exactly as the two-dimensional parameters, except that ConvolutionParameterfv is called with target CONVOLUTION_1D.
The image is formed with coordinates $i$ such that $i$ increases from left to right, starting at zero. Image location $i$ is specified by the $i$th pixel, counting from zero.

The error INVALID_VALUE is generated if $width$ is greater than the maximum supported value. This value is queried using `GetConvolutionParameteriv`, setting `target` to CONVOLUTION_1D and `pname` to MAX_CONVOLUTION_WIDTH.

Special facilities are provided for the definition of two-dimensional separable filters – filters whose image can be represented as the product of two one-dimensional images, rather than as full two-dimensional images. A two-dimensional separable convolution filter is specified with

```c
void SeparableFilter2D( enum target, enum internalformat, 
   sizei width, sizei height, enum format, enum type, 
    void *row, void *column );
```

target must be SEPARABLE_2D. internalformat specifies the formats of the table entries of the two one-dimensional images that will be retained. row points to a width pixel wide image of the specified format and type. column points to a height pixel high image, also of the specified format and type.

The two images are extracted from memory and processed as if `ConvolutionFilter1D` were called separately for each, except that each image is scaled and biased by the two-dimensional separable CONVOLUTION_FILTER_SCALE and CONVOLUTION_FILTER_BIAS parameters. These parameters are specified exactly as the one-dimensional and two-dimensional parameters, except that `ConvolutionParameteriv` is called with target SEPARABLE_2D.

Alternate Convolution Filter Specification Commands

One and two-dimensional filters may also be specified using image data taken directly from the framebuffer.

The command

```c
void CopyConvolutionFilter2D( enum target, 
    enum internalformat, int x, int y, sizei width, 
    sizei height );
```

defines a two-dimensional filter in exactly the manner of `ConvolutionFilter2D`, except that image data are taken from the framebuffer, rather than from client memory. target must be CONVOLUTION_2D. x, y, width, and height correspond precisely to the corresponding arguments of `CopyPixels` (refer to section 4.3.3); they specify the image’s width and height, and the lower left (x, y) coordinates of the framebuffer region to be copied. The image is taken from the framebuffer.
3.7. PIXEL RECTANGLES

exactly as if these arguments were passed to `CopyPixels` with argument `type` set to `COLOR`, stopping after the final expansion to RGBA.

Subsequent processing is identical to that described for `ConvolutionFilter2D`, beginning with scaling by `CONVOLUTION_FILTER_SCALE`. Parameters `target`, `internalformat`, `width`, and `height` are specified using the same values, with the same meanings, as the equivalent arguments of `ConvolutionFilter2D`. `format` is taken to be RGBA.

The command

```c
void CopyConvolutionFilter1D( enum target,
    enum internalformat, int x, int y, sizei width);
```

defines a one-dimensional filter in exactly the manner of `ConvolutionFilter1D`, except that image data are taken from the framebuffer, rather than from client memory. `target` must be `CONVOLUTION_ID`, `x`, `y`, and `width` correspond precisely to the corresponding arguments of `CopyPixels` (refer to section 4.3.3); they specify the image’s `width` and the lower left `(x, y)` coordinates of the framebuffer region to be copied. The image is taken from the framebuffer exactly as if these arguments were passed to `CopyPixels` with argument `type` set to `COLOR` and `height` set to 1, stopping after the final expansion to RGBA.

Subsequent processing is identical to that described for `ConvolutionFilter1D`, beginning with scaling by `CONVOLUTION_FILTER_SCALE`. Parameters `target`, `internalformat`, and `width` are specified using the same values, with the same meanings, as the equivalent arguments of `ConvolutionFilter2D`. `format` is taken to be RGBA.

Calling `CopyConvolutionFilter1D` or `CopyConvolutionFilter2D` will result in an `INVALID_FRAMEBUFFER_OPERATION` error if the object bound to `READ_FRAMEBUFFER_BINDING` is not framebuffer complete (see section 4.4.4).

**Convolution Filter State**

The required state for convolution filters includes a one-dimensional image array, two one-dimensional image arrays for the separable filter, and a two-dimensional image array. Each filter has associated with it a width and height (two-dimensional and separable only), an integer describing the internal format of the filter, and two groups of four floating-point numbers to store the filter scale and bias.

Each initial convolution filter is null (zero width and height, internal format RGBA, with zero-sized components). The initial value of all scale parameters is (1,1,1,1) and the initial value of all bias parameters is (0,0,0,0).
3.7. PIXEL RECTANGLES

Color Matrix Specification

Setting the matrix mode to COLOR causes the matrix operations described in section 2.12.1 to apply to the top matrix on the color matrix stack. All matrix operations have the same effect on the color matrix as they do on the other matrices.

Histogram Table Specification

The histogram table is specified with

```c
void Histogram( enum target, sizei width, 
    enum internalformat, boolean sink);
```

target must be HISTOGRAM if a histogram table is to be specified. target value PROXY_HISTOGRAM is a special case discussed later in this section. width specifies the number of entries in the histogram table, and internalformat specifies the format of each table entry. The maximum allowable width of the histogram table is implementation-dependent, but must be at least 32. sink specifies whether pixel groups will be consumed by the histogram operation (TRUE) or passed on to the minmax operation (FALSE).

If no error results from the execution of Histogram, the specified histogram table is redefined to have width entries, each with the specified internal format. The entries are indexed 0 through width – 1. Each component in each entry is set to zero. The values in the previous histogram table, if any, are lost.

The error INVALID_VALUE is generated if width is not zero or a non-negative power of two. The error TABLE_TOO_LARGE is generated if the specified histogram table is too large for the implementation. internalformat accepts the same values as the corresponding argument of ColorTable, with the exception of the values 1, 2, 3, and 4.

A GL implementation may vary its allocation of internal component resolution based on any Histogram parameter, but the allocation must not be a function of any other factor, and cannot be changed once it is established. In particular, allocations must be invariant; the same allocation must be made each time a histogram is specified with the same parameter values. These allocation rules also apply to the proxy histogram, which is described later in this section.

Histogram State and Proxy State

The state necessary for histogram operation is an array of values, with which is associated a width, an integer describing the internal format of the histogram, five integer values describing the resolutions of each of the red, green, blue, alpha,
and luminance components of the table, and a flag indicating whether or not pixel
groups are consumed by the operation. The initial array is null (zero width, internal
format RGBA, with zero-sized components). The initial value of the flag is false.

In addition to the histogram table, a partially instantiated proxy histogram table
is maintained. It includes width, internal format, and red, green, blue, alpha, and
luminance component resolutions. The proxy table does not include image data or
the flag. When Histogram is executed with target set to PROXY_HISTOGRAM, the
proxy state values are recomputed and updated. If the histogram array is too large,
no error is generated, but the proxy format, width, and component resolutions are
set to zero. If the histogram table would be accommodated by Histogram called
with target set to HISTOGRAM, the proxy state values are set exactly as though
the actual histogram table were being specified. Calling Histogram with target
PROXY_HISTOGRAM has no effect on the actual histogram table.

There is no image associated with PROXY_HISTOGRAM. It cannot be used as
a histogram, and its image must never queried using GetHistogram. The error
INVALID_ENUM results if this is attempted.

Minmax Table Specification
The minmax table is specified with

```c
void Minmax( enum target, enum internalformat,
             boolean sink );
```

target must be MINMAX. internalformat specifies the format of the table entries.
sink specifies whether pixel groups will be consumed by the minmax operation
(TRUE) or passed on to final conversion (FALSE).

internalformat accepts the same values as the corresponding argument of ColorTable, with the exception of the values 1, 2, 3, and 4, as well as the INTENSITY base and sized internal formats. The resulting table always has 2 entries, each with values corresponding only to the components of the internal format.

The state necessary for minmax operation is a table containing two elements
(the first element stores the minimum values, the second stores the maximum val-
ues), an integer describing the internal format of the table, and a flag indicating
whether or not pixel groups are consumed by the operation. The initial state is
a minimum table entry set to the maximum representable value and a maximum
table entry set to the minimum representable value. Internal format is set to RGBA
and the initial value of the flag is false.
3.7. PIXEL RECTANGLES

3.7.4 Transfer of Pixel Rectangles

The process of transferring pixels encoded in buffer object or client memory is diagrammed in figure 3.7. We describe the stages of this process in the order in which they occur.

Commands accepting or returning pixel rectangles take the following arguments (as well as additional arguments specific to their function):

- \textit{format} is a symbolic constant indicating what the values in memory represent.
- \textit{width} and \textit{height} are the width and height, respectively, of the pixel rectangle to be transferred.
- \textit{data} refers to the data to be drawn. These data are represented with one of several GL data types, specified by \textit{type}. The correspondence between the \textit{type} token values and the GL data types they indicate is given in table 3.5.

Not all combinations of \textit{format} and \textit{type} are valid. If \textit{type} is \texttt{BITMAP} and \textit{format} is not \texttt{COLOR_INDEX} or \texttt{STENCIL_INDEX} then the error \texttt{INVALID_ENUM} occurs. If \textit{format} is \texttt{DEPTH_STENCIL} and \textit{type} is not \texttt{UNSIGNED_INT_24_8} or \texttt{FLOAT_-32_UNSIGNED_INT_24_8_REV}, then the error \texttt{INVALID_ENUM} occurs. If \textit{format} is one of the integer component formats as defined in table 3.6 and \textit{type} is \texttt{FLOAT}, the error \texttt{INVALID_ENUM} occurs. Some additional constraints on the combinations of \textit{format} and \textit{type} values that are accepted are discussed below. Additional restrictions may be imposed by specific commands.

Unpacking

Data are taken from the currently bound pixel unpack buffer or client memory as a sequence of signed or unsigned bytes (GL data types \texttt{byte} and \texttt{ubyte}), signed or unsigned short integers (GL data types \texttt{short} and \texttt{ushort}), signed or unsigned integers (GL data types \texttt{int} and \texttt{uint}), or floating point values (GL data types \texttt{half} and \texttt{float}). These elements are grouped into sets of one, two, three, or four values, depending on the \textit{format}, to form a group. Table 3.6 summarizes the format of groups obtained from memory; it also indicates those formats that yield indices and those that yield floating-point or integer components.

If a pixel unpack buffer is bound (as indicated by a non-zero value of \texttt{PIXEL_UNPACK_BUFFER_BINDING}), \textit{data} is an offset into the pixel unpack buffer and the pixels are unpacked from the buffer relative to this offset; otherwise, \textit{data} is a pointer to client memory and the pixels are unpacked from client memory relative to the pointer. If a pixel unpack buffer object is bound and unpacking the pixel data according to the process described below would access memory beyond the size of the pixel unpack buffer’s memory size, an \texttt{INVALID_OPERATION} error results. If a pixel unpack buffer object is bound and \textit{data} is not evenly divisible by the number
3.7. PIXEL RECTANGLES

Figure 3.7. Transfer of pixel rectangles to the GL. Output is RGBA pixels if the GL is in RGBA mode, color index pixels otherwise. Operations in dashed boxes may be enabled or disabled. The post convolution operations are not shown. Depth and stencil pixel paths are not shown.
### Table 3.5: Pixel data type parameter values and the corresponding GL data types.

Refer to table 2.2 for definitions of GL data types. Special interpretations are described near the end of section 3.8.

</table>
of basic machine units needed to store in memory the corresponding GL data type from table 3.5 for the type parameter (or not evenly divisible by 4 for type float_32_unsigned_int_24_8_rev, which does not have a corresponding GL data type), an INVALID_OPERATION error results.

By default the values of each GL data type are interpreted as they would be specified in the language of the client’s GL binding. If UNPACK_SWAP_BYTES is enabled, however, then the values are interpreted with the bit orderings modified as per table 3.7. The modified bit orderings are defined only if the GL data type ubyte has eight bits, and then for each specific GL data type only if that type is represented with 8, 16, or 32 bits.

The groups in memory are treated as being arranged in a rectangle. This rectangle consists of a series of rows, with the first element of the first group of the first row pointed to by data. If the value of UNPACK_ROW_LENGTH is not positive, then the number of groups in a row is width; otherwise the number of groups is UNPACK_ROW_LENGTH. If p indicates the location in memory of the first element of the first row, then the first element of the Nth row is indicated by

\[ p + Nk \]  

where \( N \) is the row number (counting from zero) and \( k \) is defined as

\[ k = \begin{cases} 
  nl & s \geq a, \\
  a/s \cdot \lceil snl/a \rceil & s < a 
\end{cases} \]  

where \( n \) is the number of elements in a group, \( l \) is the number of groups in the row, \( a \) is the value of UNPACK_ALIGNMENT, and \( s \) is the size, in units of GL ubyte, of an element. If the number of bits per element is not 1, 2, 4, or 8 times the number of bits in a GL ubyte, then \( k = nl \) for all values of \( a \).

There is a mechanism for selecting a sub-rectangle of groups from a larger containing rectangle. This mechanism relies on three integer parameters:

<table>
<thead>
<tr>
<th>Element Size</th>
<th>Default Bit Ordering</th>
<th>Modified Bit Ordering</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bit</td>
<td>[7..0]</td>
<td>[7..0]</td>
</tr>
<tr>
<td>16 bit</td>
<td>[15..0]</td>
<td>[7..0][15..8]</td>
</tr>
<tr>
<td>32 bit</td>
<td>[31..0]</td>
<td>[7..0][15..8][23..16][31..24]</td>
</tr>
</tbody>
</table>

Table 3.7: Bit ordering modification of elements when UNPACK_SWAP_BYTES is enabled. These reorderings are defined only when GL data type ubyte has 8 bits, and then only for GL data types with 8, 16, or 32 bits. Bit 0 is the least significant.
Figure 3.8. Selecting a subimage from an image. The indicated parameter names are prefixed by UNPACK_ for DrawPixels and by PACK_ for ReadPixels.

UNPACK_ROW_LENGTH, UNPACK_SKIP_ROWS, and UNPACK_SKIP_PIXELS. Before obtaining the first group from memory, the data pointer is advanced by $(\text{UNPACK_SKIP_PIXELS})n + (\text{UNPACK_SKIP_ROWS})k$ elements. Then width groups are obtained from contiguous elements in memory (without advancing the pointer), after which the pointer is advanced by $k$ elements. height sets of width groups of values are obtained this way. See figure 3.8.

**Special Interpretations**

A type matching one of the types in table 3.8 is a special case in which all the components of each group are packed into a single unsigned byte, unsigned short, or unsigned int, depending on the type. If type is FLOAT_32_UNSIGNED_INT_24_8_REV, the components of each group are contained within two 32-bit words; the first word contains the float component, and the second word contains a packed 24-bit unused field, followed by an 8-bit component. The number of components per packed pixel is fixed by the type, and must match the number of components per group indicated by the format parameter, as listed in table 3.8. The error INVALID_OPERATION is generated by any command processing pixel rectangles if a mismatch occurs.

Bitfield locations of the first, second, third, and fourth components of each packed pixel type are illustrated in tables 3.9-3.12. Each bitfield is interpreted as an unsigned integer value. If the base GL type is supported with more than the minimum precision (e.g. a 9-bit byte) the packed components are right-justified

Table 3.8: Packed pixel formats.
the pixel.

Components are normally packed with the first component in the most significant bits of the bitfield, and successive component occupying progressively less significant locations. Types whose token names end with \_REV reverse the component packing order from least to most significant locations. In all cases, the most significant bit of each component is packed in the most significant bit location of its location in the bitfield.

Table 3.13: Packed pixel field assignments.

The assignment of component to fields in the packed pixel is as described in table 3.13.

Byte swapping, if enabled, is performed before the components are extracted from each pixel. The above discussions of row length and image extraction are valid for packed pixels, if “group” is substituted for “component” and the number of components per group is understood to be one.

A type of UNSIGNED_INT_10F_11F_11F_REV and format of RGB is a special case in which the data are a series of GL uint values. Each uint value specifies 3 packed components as shown in table 3.11. The 1st, 2nd, and 3rd components are called \( f_{\text{red}} \) (11 bits), \( f_{\text{green}} \) (11 bits), and \( f_{\text{blue}} \) (10 bits) respectively.

\( f_{\text{red}} \) and \( f_{\text{green}} \) are treated as unsigned 11-bit floating-point values and converted to floating-point red and green components respectively as described in section 2.1.3. \( f_{\text{blue}} \) is treated as an unsigned 10-bit floating-point value and converted to a floating-point blue component as described in section 2.1.4.

A type of UNSIGNED_INT_5_9_9_9_REV and format of RGB is a special case in which the data are a series of GL uint values. Each uint value specifies 4 packed components as shown in table 3.11. The 1st, 2nd, 3rd, and 4th components are called \( p_{\text{red}} \), \( p_{\text{green}} \), \( p_{\text{blue}} \), and \( p_{\text{exp}} \) respectively and are treated as unsigned integers. These are then used to compute floating-point RGB components (ignoring the “Conversion to floating-point” section below in this case) as follows:

\[
\begin{align*}
\text{red} &= p_{\text{red}}2^{p_{\text{exp}}-B-N} \\
\text{green} &= p_{\text{green}}2^{p_{\text{exp}}-B-N} \\
\text{blue} &= p_{\text{blue}}2^{p_{\text{exp}}-B-N}
\end{align*}
\]

where \( B = 15 \) (the exponent bias) and \( N = 9 \) (the number of mantissa bits).
Conversion to floating-point

This step applies only to groups of floating-point components. It is not performed on indices or integer components. For groups containing both components and indices, such as `DEPTH_STENCIL`, the indices are not converted.

Each element in a group is converted to a floating-point value. For unsigned integer elements, equation 2.1 is used. For signed integer elements, equation 2.2 is used unless the final destination of the transferred element is a texture or framebuffer component in one of the `SNORM` formats described in table 3.17, in which case equation 2.3 is used instead.

Conversion to RGB

This step is applied only if the `format` is `LUMINANCE` or `LUMINANCE_ALPHA`. If the `format` is `LUMINANCE`, then each group of one element is converted to a group of R, G, and B (three) elements by copying the original single element into each of the three new elements. If the `format` is `LUMINANCE_ALPHA`, then each group of two elements is converted to a group of R, G, B, and A (four) elements by copying the first original element into each of the first three new elements and copying the second original element to the A (fourth) new element.

Final Expansion to RGBA

This step is performed only for non-depth component groups. Each group is converted to a group of 4 elements as follows: if a group does not contain an A element, then A is added and set to 1 for integer components or 1.0 for floating-point components. If any of R, G, or B is missing from the group, each missing element is added and assigned a value of 0 for integer components or 0.0 for floating-point components.

Pixel Transfer Operations

This step is actually a sequence of steps. Because the pixel transfer operations are performed equivalently during the drawing, copying, and reading of pixels, and during the specification of texture images (either from memory or from the framebuffer), they are described separately in section 3.7.6. After the processing described in that section is completed, groups are processed as described in the following sections.
3.7. PIXEL RECTANGLES

3.7.5 Rasterization of Pixel Rectangles

Pixels are drawn using

```c
void DrawPixels( sizei width, sizei height, enum format,
    enum type, void *data );
```

If the GL is in color index mode and `format` is not one of `COLOR_INDEX, STENCIL_INDEX, DEPTH_COMPONENT, or DEPTH_STENCIL`, then the error `INVALID_OPERATION` occurs. Results of rasterization are undefined if any of the selected draw buffers of the draw framebuffer have an integer format and no fragment shader is active. If `format` contains integer components, as shown in table 3.6, an `INVALID_OPERATION` error is generated.

Calling `DrawPixels` will result in an `INVALID_FRAMEBUFFER_OPERATION` error if the object bound to `DRAW_FRAMEBUFFER_BINDING` is not framebuffer complete (see section 4.4.4).

Calling `DrawPixels` with a `type` of `BITMAP` is a special case in which the data are a series of GL `ubyte` values. Each `ubyte` value specifies 8 1-bit elements with its 8 least-significant bits. The 8 single-bit elements are ordered from most significant to least significant if the value of `UNPACK_LSB_FIRST` is `FALSE`; otherwise, the ordering is from least significant to most significant. The values of bits other than the 8 least significant in each `ubyte` are not significant.

The first element of the first row is the first bit (as defined above) of the `ubyte` pointed to by the pointer passed to `DrawPixels`. The first element of the second row is the first bit (again as defined above) of the `ubyte` at location `p + k`, where `k` is computed as

\[
k = a \left\lceil \frac{l}{8a} \right\rceil \quad (3.16)
\]

There is a mechanism for selecting a sub-rectangle of elements from a `BITMAP` image as well. Before obtaining the first element from memory, the pointer supplied to `DrawPixels` is effectively advanced by `UNPACK_SKIP_ROWS * k` `ubytess`. Then `UNPACK_SKIP_PIXELS` 1-bit elements are ignored, and the subsequent `width` 1-bit elements are obtained, without advancing the `ubyte` pointer, after which the pointer is advanced by `k` `ubytess`. `height` sets of `width` elements are obtained this way.

Once pixels are transferred, `DrawPixels` performs final conversion on pixel values, then converts them to fragments as described below. Fragments generated by `DrawPixels` are then processed in the same fashion as fragments generated by rasterization of a primitive.
3.7. PIXEL RECTANGLES

Final Conversion

For a color index, final conversion consists of masking the bits of the index to the left of the binary point by $2^n - 1$, where $n$ is the number of bits in an index buffer.

For integer RGBA components, no conversion is performed. For floating-point RGBA components, if fragment color clamping is enabled, each element is clamped to $[0, 1]$, and may be converted to fixed-point according to equation 2.4. If fragment color clamping is disabled, RGBA components are unmodified. Fragment color clamping is controlled by calling

```c
void ClampColor( enum target, enum clamp );
```

with `target` set to `CLAMP_FRAGMENT_COLOR`. If `clamp` is `TRUE`, fragment color clamping is enabled; if `clamp` is `FALSE`, fragment color clamping is disabled. If `clamp` is `FIXED_ONLY`, fragment color clamping is enabled if all enabled color buffers have fixed-point components.

For a depth component, an element is processed according to the depth buffer’s representation. For fixed-point depth buffers, the element is first clamped to the range $[0, 1]$ and then converted to fixed-point as if it were a window $z$ value (see section 2.16.1). Conversion is not necessary when the depth buffer uses a floating-point representation, but clamping is.

Stencil indices are masked by $2^n - 1$, where $n$ is the number of bits in the stencil buffer.

The state required for fragment color clamping is a three-valued integer. The initial value of fragment color clamping is `FIXED_ONLY`.

Conversion to Fragments

The conversion of a group to fragments is controlled with

```c
void PixelZoom( float zx, float zy );
```

Let $(x_{rp}, y_{rp})$ be the current raster position (section 2.24). (If the current raster position is invalid, then `DrawPixels` is ignored; pixel transfer operations do not update the histogram or minmax tables, and no fragments are generated. However, the histogram and minmax tables are updated even if the corresponding fragments are later rejected by the pixel ownership (section 4.1.1) or scissor (section 4.1.2) tests.) If a particular group (index or components) is the $n$th in a row and belongs to the $m$th row, consider the region in window coordinates bounded by the rectangle with corners

$$(x_{rp} + z_x n, y_{rp} + z_y m) \quad \text{and} \quad (x_{rp} + z_x (n + 1), y_{rp} + z_y (m + 1))$$
(either \(z_x\) or \(z_y\) may be negative). A fragment representing group \((n, m)\) is produced for each framebuffer pixel inside, or on the bottom or left boundary, of this rectangle.

A fragment arising from a group consisting of color data takes on the color index or color components of the group and the current raster position’s associated depth value, while a fragment arising from a depth component takes that component’s depth value and the current raster position’s associated color index or color components. In both cases, the fog coordinate is taken from the current raster position’s associated raster distance, the secondary color is taken from the current raster position’s associated secondary color, and texture coordinates are taken from the current raster position’s associated texture coordinates. Groups arising from DrawPixels with a format of DEPTH_STENCIL or STENCIL_INDEX are treated specially and are described in section 4.3.1.

### 3.7.6 Pixel Transfer Operations

The GL defines six kinds of pixel groups:

1. **Floating-point RGBA component**: Each group comprises four color components in floating-point format: red, green, blue, and alpha.

2. **Integer RGBA component**: Each group comprises four color components in integer format: red, green, blue, and alpha.

3. **Depth component**: Each group comprises a single depth component.

4. **Color index**: Each group comprises a single color index.

5. **Stencil index**: Each group comprises a single stencil index.

6. **Depth/stencil**: Each group comprises a single depth component and a single stencil index.

Each operation described in this section is applied sequentially to each pixel group in an image. Many operations are applied only to pixel groups of certain kinds; if an operation is not applicable to a given group, it is skipped. None of the operations defined in this section affect integer RGBA component pixel groups.

This step applies only to RGBA component and depth component groups, and to the depth components in depth/stencil groups. Each component is multiplied by an appropriate signed scale factor: \(\text{RED\_SCALE}\) for an R component, \(\text{GREEN\_SCALE}\) for a G component, \(\text{BLUE\_SCALE}\) for an A component, or \(\text{ALPHA\_SCALE}\) for an A component, or \(\text{DEPTH\_SCALE}\) for a depth component. Then the result
is added to the appropriate signed bias: \texttt{RED\_BIAS}, \texttt{GREEN\_BIAS}, \texttt{BLUE\_BIAS}, \texttt{ALPHA\_BIAS}, or \texttt{DEPTH\_BIAS}.

\subsection*{Arithmetic on Indices}

This step applies only to color index and stencil index groups, and to the stencil indices in depth/stencil groups. If the index is a floating-point value, it is converted to fixed-point, with an unspecified number of bits to the right of the binary point and at least $\lceil \log_2(\text{MAX\_PIXEL\_MAP\_TABLE}) \rceil$ bits to the left of the binary point. Indices that are already integers remain so; any fraction bits in the resulting fixed-point value are zero.

The fixed-point index is then shifted by $|\text{INDEX\_SHIFT}|$ bits, left if $\text{INDEX\_SHIFT} > 0$ and right otherwise. In either case the shift is zero-filled. Then, the signed integer offset \texttt{INDEX\_OFFSET} is added to the index.

\subsection*{RGBA to RGBA Lookup}

This step applies only to RGBA component groups, and is skipped if \texttt{MAP\_COLOR} is \texttt{FALSE}. First, each component is clamped to the range $[0, 1]$. There is a table associated with each of the R, G, B, and A component elements: \texttt{PIXEL\_MAP\_R\_TO\_R} for R, \texttt{PIXEL\_MAP\_G\_TO\_G} for G, \texttt{PIXEL\_MAP\_B\_TO\_B} for B, and \texttt{PIXEL\_MAP\_A\_TO\_A} for A. Each element is multiplied by an integer one less than the size of the corresponding table, and, for each element, an address is found by rounding this value to the nearest integer. For each element, the addressed value in the corresponding table replaces the element.

\subsection*{Color Index Lookup}

This step applies only to color index groups. If the GL command that invokes the pixel transfer operation requires that RGBA component pixel groups be generated, then a conversion is performed at this step. RGBA component pixel groups are required if

\begin{enumerate}
  \item The groups will be rasterized, and the GL is in RGBA mode, or
  \item The groups will be loaded as an image into texture memory, or
  \item The groups will be returned to client memory with a format other than \texttt{COLOR\_INDEX}.
\end{enumerate}

If RGBA component groups are required, then the integer part of the index is used to reference 4 tables of color components: \texttt{PIXEL\_MAP\_I\_TO\_R}, \texttt{PIXEL\_MAP\_I\_TO\_G}, \texttt{PIXEL\_MAP\_I\_TO\_B}, and \texttt{PIXEL\_MAP\_I\_TO\_A}. Each of these tables
must have \(2^n\) entries for some integer value of \(n\) (\(n\) may be different for each table). For each table, the index is first rounded to the nearest integer; the result is ANDed with \(2^n - 1\), and the resulting value used as an address into the table. The indexed value becomes an R, G, B, or A value, as appropriate. The group of four elements so obtained replaces the index, changing the group’s type to RGBA component.

If RGBA component groups are not required, and if \texttt{MAP\_COLOR} is enabled, then the index is looked up in the \texttt{PIXEL\_MAP\_I\_TO\_I} table (otherwise, the index is not looked up). Again, the table must have \(2^n\) entries for some integer \(n\). The index is first rounded to the nearest integer; the result is ANDed with \(2^n - 1\), and the resulting value used as an address into the table. The value in the table replaces the index. The floating-point table value is first rounded to a fixed-point value with unspecified precision. The group’s type remains color index.

**Stencil Index Lookup**

This step applies only to stencil index groups, and to the stencil indices in depth/stencil groups. If \texttt{MAP\_STENCIL} is enabled, then the index is looked up in the \texttt{PIXEL\_MAP\_S\_TO\_S} table (otherwise, the index is not looked up). The table must have \(2^n\) entries for some integer \(n\). The integer index is ANDed with \(2^n - 1\), and the resulting value used as an address into the table. The integer value in the table replaces the index.

**Color Table Lookup**

This step applies only to RGBA component groups. Color table lookup is only done if \texttt{COLOR\_TABLE} is enabled. If a zero-width table is enabled, no lookup is performed.

The internal format of the table determines which components of the group will be replaced (see table 3.14). The components to be replaced are converted to indices by clamping to \([0, 1]\), multiplying by an integer one less than the width of the table, and rounding to the nearest integer. Components are replaced by the table entry at the index.

The required state is one bit indicating whether color table lookup is enabled or disabled. In the initial state, lookup is disabled.

**Convolution**

This step applies only to RGBA component groups. If \texttt{CONVOLUTION\_1D} is enabled, the one-dimensional convolution filter is applied only to the one-

#### Table 3.14: Color table lookup. $R_t$, $G_t$, $B_t$, $A_t$, and $I_t$ are color table values that are assigned to pixel components $R$, $G$, $B$, and $A$ depending on the table format. When there is no assignment, the component value is left unchanged by lookup.

Dimensional texture images passed to `TexImage1D`, `texSubImage1D`, `CopyTexImage1D`, and `CopyTexSubImage1D`. If `CONVOLUTION_2D` is enabled, the two-dimensional convolution filter is applied only to the two-dimensional images passed to `DrawPixels`, `CopyPixels`, `ReadPixels`, `TexImage2D`, `TexSubImage2D`, `CopyTexImage2D`, `CopyTexSubImage2D`, and `CopyTexSubImage3D`. If `SEPARABLE_2D` is enabled, and `CONVOLUTION_2D` is disabled, the separable two-dimensional convolution filter is instead applied these images.

The convolution operation is a sum of products of source image pixels and convolution filter pixels. Source image pixels always have four components: red, green, blue, and alpha, denoted in the equations below as $R_s$, $G_s$, $B_s$, and $A_s$. Filter pixels may be stored in one of five formats, with 1, 2, 3, or 4 components. These components are denoted as $R_f$, $G_f$, $B_f$, $A_f$, $L_f$, and $I_f$ in the equations below. The result of the convolution operation is the 4-tuple $R, G, B, A$. Depending on the internal format of the filter, individual color components of each source image pixel are convolved with one filter component, or are passed unmodified. The rules for this are defined in table 3.15.

The convolution operation is defined differently for each of the three convolution filters. The variables $W_f$ and $H_f$ refer to the dimensions of the convolution filter. The variables $W_s$ and $H_s$ refer to the dimensions of the source pixel image.

The convolution equations are defined as follows, where $C$ refers to the filtered result, $C_f$ refers to the one- or two-dimensional convolution filter, and $C_{row}$ and $C_{column}$ refer to the two one-dimensional filters comprising the two-dimensional separable filter. $C'_s$ depends on the source image color $C_s$ and the convolution border mode as described below. $C_r$, the filtered output image, depends on all of these variables and is described separately for each border mode. The pixel indexing...
Table 3.15: Computation of filtered color components depending on filter image format. \( C \ast F \) indicates the convolution of image component \( C \) with filter \( F \).

The convolution border mode for a specific convolution filter is specified by calling

```c
void ConvolutionParameter(if)( enum target, enum pname, T param );
```

where \( target \) is the name of the filter, \( pname \) is CONVOLUTION_BORDER_MODE, and \( param \) is one of REDUCE, CONSTANT_BORDER or REPLICATE_BORDER.
Border Mode \texttt{REDUCE}

The width and height of source images convolved with border mode \texttt{REDUCE} are reduced by $W_f - 1$ and $H_f - 1$, respectively. If this reduction would generate a resulting image with zero or negative width and/or height, the output is simply null, with no error generated. The coordinates of the image that results from a convolution with border mode \texttt{REDUCE} are zero through $W_s - W_f$ in width, and zero through $H_s - H_f$ in height. In cases where errors can result from the specification of invalid image dimensions, it is these resulting dimensions that are tested, not the dimensions of the source image. (A specific example is \texttt{TexImage1D} and \texttt{TexImage2D}, which specify constraints for image dimensions. Even if \texttt{TexImage1D} or \texttt{TexImage2D} is called with a null pixel pointer, the dimensions of the resulting texture image are those that would result from the convolution of the specified image).

When the border mode is \texttt{REDUCE}, $C'_s$ equals the source image color $C_s$ and $C_r$ equals the filtered result $C$. For the remaining border modes, define $C_w = \lfloor W_f/2 \rfloor$ and $C_h = \lfloor H_f/2 \rfloor$. The coordinates $(C_w, C_h)$ define the center of the convolution filter.

Border Mode \texttt{CONSTANT\_BORDER}

If the convolution border mode is \texttt{CONSTANT\_BORDER}, the output image has the same dimensions as the source image. The result of the convolution is the same as if the source image were surrounded by pixels with the same color as the current convolution border color. Whenever the convolution filter extends beyond one of the edges of the source image, the constant-color border pixels are used as input to the filter. The current convolution border color is set by calling \texttt{ConvolutionParameterfv} or \texttt{ConvolutionParameteriv} with \texttt{pname} set to \texttt{CONVOLUTION\_BORDER\_COLOR} and \texttt{params} containing four values that comprise the RGBA color to be used as the image border. Integer color components are interpreted linearly such that the largest positive integer maps to 1.0, and the smallest negative integer maps to -1.0. Floating point color components are not clamped when they are specified.

For a one-dimensional filter, the result color is defined by

$$
C_r[i] = C[i - C_w]
$$

where $C[i']$ is computed using the following equation for $C'_s[i']$:

$$
C'_s[i'] = \begin{cases} 
C_s[i'], & 0 \leq i' < W_s \\
C_c, & \text{otherwise}
\end{cases}
$$
and $C_c$ is the convolution border color.

For a two-dimensional or two-dimensional separable filter, the result color is defined by

$$C_r[i, j] = C[i - C_w, j - C_h]$$

where $C[i', j']$ is computed using the following equation for $C_s[i', j']$:

$$C_s[i', j'] = \begin{cases} 
C_s[i', j'], & 0 \leq i' < W_s, 0 \leq j' < H_s \\
C_c, & \text{otherwise}
\end{cases}$$

**Border Mode** `REPLICATE_BORDER`

The convolution border mode `REPLICATE_BORDER` also produces an output image with the same dimensions as the source image. The behavior of this mode is identical to that of the `CONSTANT_BORDER` mode except for the treatment of pixel locations where the convolution filter extends beyond the edge of the source image. For these locations, it is as if the outermost one-pixel border of the source image was replicated. Conceptually, each pixel in the leftmost one-pixel column of the source image is replicated $C_w$ times to provide additional image data along the left edge, each pixel in the rightmost one-pixel column is replicated $C_w$ times to provide additional image data along the right edge, and each pixel value in the top and bottom one-pixel rows is replicated to create $C_h$ rows of image data along the top and bottom edges. The pixel value at each corner is also replicated in order to provide data for the convolution operation at each corner of the source image.

For a one-dimensional filter, the result color is defined by

$$C_r[i] = C[i - C_w]$$

where $C[i']$ is computed using the following equation for $C_s[i']$:

$$C_s[i'] = C_s[\text{clamp}(i', W_s)]$$

and the clamping function $\text{clamp}(val, max)$ is defined as

$$\text{clamp}(val, max) = \begin{cases} 
0, & val < 0 \\
val, & 0 \leq val < max \\
max - 1, & val \geq max
\end{cases}$$

For a two-dimensional or two-dimensional separable filter, the result color is defined by

$$C_r[i, j] = C[i - C_w, j - C_h]$$
where $C[i', j']$ is computed using the following equation for $C'_s[i', j']$:

$$C'_s[i', j'] = C_s[\text{clamp}(i', W_s), \text{clamp}(j', H_s)]$$

If a convolution operation is performed, each component of the resulting image is scaled by the corresponding PixelTransfer parameters: POST_CONVOLUTION_RED_SCALE for an R component, POST_CONVOLUTION_GREEN_SCALE for a G component, POST_CONVOLUTION_BLUE_SCALE for a B component, and POST_CONVOLUTION_ALPHA_SCALE for an A component. The result is added to the corresponding bias: POST_CONVOLUTION_RED_BIAS, POST_CONVOLUTION_GREEN_BIAS, POST_CONVOLUTION_BLUE_BIAS, or POST_CONVOLUTION_ALPHA_BIAS.

The required state is three bits indicating whether each of one-dimensional, two-dimensional, or separable two-dimensional convolution is enabled or disabled, an integer describing the current convolution border mode, and four floating-point values specifying the convolution border color. In the initial state, all convolution operations are disabled, the border mode is REDUCE, and the border color is $(0, 0, 0, 0)$.

Post Convolution Color Table Lookup

This step applies only to RGBA component groups. Post convolution color table lookup is enabled or disabled by calling Enable or Disable with the symbolic constant POST_CONVOLUTION_COLOR_TABLE. The post convolution table is defined by calling ColorTable with a target argument of POST_CONVOLUTION_COLOR_TABLE. In all other respects, operation is identical to color table lookup, as defined earlier in section 3.7.6.

The required state is one bit indicating whether post convolution table lookup is enabled or disabled. In the initial state, lookup is disabled.

Color Matrix Transformation

This step applies only to RGBA component groups. The components are transformed by the color matrix. Each transformed component is multiplied by an appropriate signed scale factor: POST_COLOR_MATRIX_RED_SCALE for an R component, POST_COLOR_MATRIX_GREEN_SCALE for a G component, POST_COLOR_MATRIX_BLUE_SCALE for a B component, and POST_COLOR_MATRIX_ALPHA_SCALE for an A component. The result is added to a signed bias: POST_COLOR_MATRIX_RED_BIAS, POST_COLOR_MATRIX_GREEN_BIAS, POST_COLOR_MATRIX_BLUE_BIAS, or POST_COLOR_MATRIX_ALPHA_BIAS.
The resulting components replace each component of the original group.

That is, if \( M_c \) is the color matrix, a subscript of \( s \) represents the scale term for a component, and a subscript of \( b \) represents the bias term, then the components

\[
\begin{pmatrix}
R \\
G \\
B \\
A
\end{pmatrix}
\]

are transformed to

\[
\begin{pmatrix}
R' \\
G' \\
B' \\
A'
\end{pmatrix} = \begin{pmatrix}
R_s & 0 & 0 & 0 \\
0 & G_s & 0 & 0 \\
0 & 0 & B_s & 0 \\
0 & 0 & 0 & A_s
\end{pmatrix} M_c \begin{pmatrix}
R \\
G \\
B \\
A
\end{pmatrix} + \begin{pmatrix}
R_b \\
G_b \\
B_b \\
A_b
\end{pmatrix}.
\]

**Post Color Matrix Color Table Lookup**

This step applies only to RGBA component groups. Post color matrix color table lookup is enabled or disabled by calling `Enable` or `Disable` with the symbolic constant `POST_COLOR_MATRIX_COLOR_TABLE`. The post color matrix table is defined by calling `ColorTable` with a target argument of `POST_COLOR_MATRIX_COLOR_TABLE`. In all other respects, operation is identical to color table lookup, as defined in section 3.7.6.

The required state is one bit indicating whether post color matrix lookup is enabled or disabled. In the initial state, lookup is disabled.

**Histogram**

This step applies only to RGBA component groups. Histogram operation is enabled or disabled by calling `Enable` or `Disable` with the symbolic constant `HISTOGRAM`.

If the width of the table is non-zero, then indices \( R_i, G_i, B_i, \) and \( A_i \) are derived from the red, green, blue, and alpha components of each pixel group (without modifying these components) by clamping each component to \([0, 1]\), multiplying by one less than the width of the histogram table, and rounding to the nearest integer. If the format of the `HISTOGRAM` table includes red or luminance, the red or luminance component of histogram entry \( R_i \) is incremented by one. If the format of the `HISTOGRAM` table includes green, the green component of histogram entry \( G_i \) is incremented by one. The blue and alpha components of histogram entries
3.7. PIXEL RECTANGLES

If the Histogram sink parameter is FALSE, histogram operation has no effect on the stream of pixel groups being processed. Otherwise, all RGBA pixel groups are discarded immediately after the histogram operation is completed. Because histogram precedes minmax, no minmax operation is performed. No pixel fragments are generated, no change is made to texture memory contents, and no pixel values are returned. However, texture object state is modified whether or not pixel groups are discarded.

Minmax

This step applies only to RGBA component groups. Minmax operation is enabled or disabled by calling Enable or Disable with the symbolic constant MINMAX.

If the format of the minmax table includes red or luminance, the red component value replaces the red or luminance value in the minimum table element if and only if it is less than that component. Likewise, if the format includes red or luminance and the red component of the group is greater than the red or luminance value in the maximum element, the red group component replaces the red or luminance maximum component. If the format of the table includes green, the green group component conditionally replaces the green minimum and/or maximum if it is smaller or larger, respectively. The blue and alpha group components are similarly tested and replaced, if the table format includes blue and/or alpha. The internal type of the minimum and maximum component values is floating point, with at least the same representable range as a floating point number used to represent colors (section 2.1.1). There are no semantics defined for the treatment of group component values that are outside the representable range.

If the Minmax sink parameter is FALSE, minmax operation has no effect on the stream of pixel groups being processed. Otherwise, all RGBA pixel groups are discarded immediately after the minmax operation is completed. No pixel fragments are generated, no change is made to texture memory contents, and no pixel values are returned. However, texture object state is modified whether or not pixel groups are discarded.

3.7.7 Pixel Rectangle Multisample Rasterization

If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one, then pixel rectangles are rasterized using the following algorithm. Let \((X_{rp}, Y_{rp})\) be the current raster position. (If the current raster position is invalid, then DrawPixels is
ignored.) If a particular group (index or components) is the $n$th in a row and belongs to the $m$th row, consider the region in window coordinates bounded by the rectangle with corners

$$(X_{rp} + Z_x \ast n, Y_{rp} + Z_y \ast m)$$

and

$$(X_{rp} + Z_x \ast (n + 1), Y_{rp} + Z_y \ast (m + 1))$$

where $Z_x$ and $Z_y$ are the pixel zoom factors specified by PixelZoom, and may each be either positive or negative. A fragment representing group $(n, m)$ is produced for each framebuffer pixel with one or more sample points that lie inside, or on the bottom or left boundary, of this rectangle. Each fragment so produced takes its associated data from the group and from the current raster position, in a manner consistent with the discussion in the Conversion to Fragments subsection of section 3.7.5. All depth and color sample values are assigned the same value, taken either from their group (for depth and color component groups) or from the current raster position (if they are not). All sample values are assigned the same fog coordinate and the same set of texture coordinates, taken from the current raster position.

A single pixel rectangle will generate multiple, perhaps very many fragments for the same framebuffer pixel, depending on the pixel zoom factors.

### 3.8 Bitmaps

Bitmaps are rectangles of zeros and ones specifying a particular pattern of fragments to be produced. Each of these fragments has the same associated data. These data are those associated with the current raster position.

Bitmaps are sent using

```c
void Bitmap(sizei w, sizei h, float xbo, float ybo,
            float xbi, float ybi, ubyte *data);
```

$w$ and $h$ comprise the integer width and height of the rectangular bitmap, respectively. $(x_{bo}, y_{bo})$ gives the floating-point $x$ and $y$ values of the bitmap’s origin. $(x_{bi}, y_{bi})$ gives the floating-point $x$ and $y$ increments that are added to the raster position after the bitmap is rasterized. $data$ is a pointer to a bitmap.

Like a polygon pattern, a bitmap is unpacked from memory according to the procedure given in section 3.7.5 for DrawPixels; it is as if the width and height passed to that command were equal to $w$ and $h$, respectively, the type were BITMAP, and the format were COLOR_INDEX. The unpacked values (before any conversion...
or arithmetic would have been performed) form a stipple pattern of zeros and ones. See figure 3.9.

A bitmap sent using `Bitmap` is rasterized as follows. First, if the current raster position is invalid (the valid bit is reset), the bitmap is ignored. Otherwise, a rectangular array of fragments is constructed, with lower left corner at

\[(x_{ll}, y_{ll}) = (\lfloor x_{rp} - x_{bo} \rfloor, \lfloor y_{rp} - y_{bo} \rfloor)\]

and upper right corner at \((x_{ll} + w, y_{ll} + h)\) where \(w\) and \(h\) are the width and height of the bitmap, respectively. Fragments in the array are produced if the corresponding bit in the bitmap is 1 and not produced otherwise. The associated data for each fragment are those associated with the current raster position. Once the fragments have been produced, the current raster position is updated:

\[ (x_{rp}, y_{rp}) \leftarrow (x_{rp} + x_{bi}, y_{rp} + y_{bi}) \]

The \(z\) and \(w\) values of the current raster position remain unchanged.

Calling `Bitmap` will result in an `INVALID_FRAMEBUFFER_OPERATION` error if the object bound to `DRAW_FRAMEBUFFER_BINDING` is not framebuffer complete (see section 4.4.4).
3.9. TEXTURING

Bitmap Multisample Rasterization

If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one, then bitmaps are rasterized using the following algorithm. If the current raster position is invalid, the bitmap is ignored. Otherwise, a screen-aligned array of pixel-size rectangles is constructed, with its lower left corner at \((X_{rp}, Y_{rp})\), and its upper right corner at \((X_{rp} + w, Y_{rp} + h)\), where \(w\) and \(h\) are the width and height of the bitmap. Rectangles in this array are eliminated if the corresponding bit in the bitmap is 0, and are retained otherwise. Bitmap rasterization produces a fragment for each framebuffer pixel with one or more sample points either inside or on the bottom or left edge of a retained rectangle.

Coverage bits that correspond to sample points either inside or on the bottom or left edge of a retained rectangle are 1, other coverage bits are 0. The associated data for each sample are those associated with the current raster position. Once the fragments have been produced, the current raster position is updated exactly as it is in the single-sample rasterization case.

3.9 Texturing

Texturing maps a portion of one or more specified images onto each primitive for which texturing is enabled. This mapping is accomplished in shaders by sampling the color of an image at the location indicated by specified \((s, t, r)\) texture coordinates. It is accomplished in fixed-function processing by using the color of an image at the location indicated by a texture coordinate set’s \((s, t, r, q)\) values. Texture lookups are typically used to modify a fragment’s RGBA color but may be used for any purpose in a shader.

The internal data type of a texture may be signed or unsigned normalized fixed-point, signed or unsigned integer, or floating-point, depending on the internal format of the texture. The correspondence between the internal format and the internal data type is given in tables 3.17-3.19. Fixed-point and floating-point textures return a floating-point value and integer textures return signed or unsigned integer values. When a fragment shader is active, the shader is responsible for interpreting the result of a texture lookup as the correct data type, otherwise the result is undefined. When not using a fragment shader, floating-point texture values are assumed, and the results of using either signed normalized fixed-point or integer textures in this case are undefined.

Each of the supported types of texture is a collection of images built from one-, two-, or three-dimensional arrays of image elements referred to as texels. One-, two-, and three-dimensional textures consist respectively of one-, two-, or three-dimensional texel arrays. One- and two-dimensional array textures are ar-
rays of one- or two-dimensional images, consisting of one or more layers. Two-dimensional multisample and two-dimensional multisample array textures are special two-dimensional and two-dimensional array textures, respectively, containing multiple samples in each texel. Cube maps are special two-dimensional array textures with six layers that represent the faces of a cube. When accessing a cube map, the texture coordinates are projected onto one of the six faces of the cube. Rectangular textures are special two-dimensional textures consisting of only a single image and accessed using unnormalized coordinates. Buffer textures are special one-dimensional textures whose texel arrays are stored in separate buffer objects.

Implementations must support texturing using multiple images. Each fragment or vertex carries multiple sets of texture coordinates \((s, t, r, q)\) which are used to index separate images to produce color values which are collectively used to modify the resulting transformed vertex or fragment color. Texturing is specified only for RGBA mode; its use in color index mode is undefined. The following subsections (up to and including section 3.9.9) specify the GL operation with a single texture. Section 3.9.19 specifies the details of how multiple texture units interact.

The GL provides two ways to specify the details of how texturing of a primitive is effected. The first is referred to as fixed-function fragment shading, or simply fixed-function, and is described in this section. The second is referred to as a fragment shader, and is described in section 3.12. The specification of the image to be texture mapped and the means by which the image is filtered when applied to the primitive are common to both methods and are discussed in this section. The fixed-function method for determining what RGBA value is produced is also described in this section. If a fragment shader is active, the method for determining the RGBA value is specified by an application-supplied fragment shader as described in the OpenGL Shading Language Specification.

When no fragment shader is active, the coordinates used for texturing are \((s/q, t/q, r/q)\), derived from the original texture coordinates \((s, t, r, q)\). If the \(q\) texture coordinate is less than or equal to zero, the coordinates used for texturing are undefined. When a fragment shader is active, the \((s, t, r, q)\) coordinates are available to the fragment shader. The coordinates used for texturing in a fragment shader are defined by the OpenGL Shading Language Specification.

The command

```c
void ActiveTexture( enum texture );
```

specifies the active texture unit selector, ACTIVE_TEXTURE. Each texture unit contains up to two distinct sub-units: a texture coordinate processing unit consisting of a texture matrix stack and texture coordinate generation state and a texture image unit consisting of all the texture state defined in section 3.9. In implementations
3.9. TEXTURING

with a different number of supported texture coordinate sets and texture image units, some texture units may consist of only one of the two sub-units.

The active texture unit selector selects the texture image unit accessed by commands involving texture image processing (section 3.9). Such commands include all variants of TexEnv (except for those controlling point sprite coordinate replacement), TexParameter, TexImage, BindTexture, Enable/Disable for any texture target (e.g., TEXTURE_2D), and queries of all such state. If the texture image unit number corresponding to the current value of ACTIVE_TEXTURE is greater than or equal to the implementation-dependent constant MAX_COMBINED_TEXTURE_IMAGE_UNITS, the error INVALID_OPERATION is generated by any such command.

The active texture unit selector also specifies the texture coordinate set accessed by commands involving texture coordinate processing (see section 2.12.1).

ActiveTexture generates the error INVALID_ENUM if an invalid texture is specified. texture is a symbolic constant of the form TEXTUREi, indicating that texture unit i is to be modified. The constants obey TEXTUREi = TEXTURE0 + i (i is in the range 0 to k – 1, where k is the larger of the values of MAX_TEXTURE_COORDS and MAX_COMBINED_TEXTURE_IMAGE_UNITS).

For backwards compatibility, the implementation-dependent constant MAX_TEXTURE_UNITS specifies the number of conventional texture units supported by the implementation. Its value must be no larger than the minimum of MAX_TEXTURE_COORDS and MAX_COMBINED_TEXTURE_IMAGE_UNITS.

The state required for the active texture image unit selector is a single integer. The initial value is TEXTURE0.

3.9.1  Texture Image Specification

The command

```
void TexImage3D( enum target, int level, int internalformat,
    sizei width, sizei height, sizei depth, int border,
    enum format, enum type, void *data );
```

is used to specify a three-dimensional texture image. target must be one of TEXTURE_3D for a three-dimensional texture or TEXTURE_2D_ARRAY for an two-dimensional array texture. Additionally, target may be either PROXY_TEXTURE_3D for a three-dimensional proxy texture, or PROXY_TEXTURE_2D_ARRAY for a two-dimensional proxy array texture, as discussed in section 3.9.13. format, type, and data specify the format of the image data, the type of those data, and a reference to the image data in the currently bound pixel unpack buffer or client memory, as described in section 3.7.4. The format STENCIL_INDEX is not allowed.
The groups in memory are treated as being arranged in a sequence of adjacent rectangles. Each rectangle is a two-dimensional image, whose size and organization are specified by the width and height parameters to TexImage3D. The values of UNPACK_ROW_LENGTH and UNPACK_ALIGNMENT control the row-to-row spacing in these images as described in section 3.7.4. If the value of the integer parameter UNPACK_IMAGE_HEIGHT is not positive, then the number of rows in each two-dimensional image is height; otherwise the number of rows is UNPACK_IMAGE_HEIGHT. Each two-dimensional image comprises an integral number of rows, and is exactly adjacent to its neighbor images.

The mechanism for selecting a sub-volume of a three-dimensional image relies on the integer parameter UNPACK_SKIP_IMAGES. If UNPACK_SKIP_IMAGES is positive, the pointer is advanced by UNPACK_SKIP_IMAGES times the number of elements in one two-dimensional image before obtaining the first group from memory. Then depth two-dimensional images are processed, each having a subimage extracted as described in section 3.7.4.

The selected groups are transferred to the GL as described in section 3.7.4 and then clamped to the representable range of the internal format. If the internalformat of the texture is signed or unsigned integer, components are clamped to \([-2^{n-1}, 2^{n-1} - 1]\) or \([0, 2^n - 1]\), respectively, where \(n\) is the number of bits per component. For color component groups, if the internalformat of the texture is signed or unsigned normalized fixed-point, components are clamped to \([-1, 1]\) or \([0, 1]\), respectively. For depth component groups, the depth value is clamped to \([0, 1]\). Otherwise, values are not modified. Stencil index values are masked by \(2^n - 1\), where \(n\) is the number of stencil bits in the internal format resolution (see below). If the base internal format is DEPTH_STENCIL and format is not DEPTH_STENCIL, then the values of the stencil index texture components are undefined.

Components are then selected from the resulting R, G, B, A, depth, or stencil values to obtain a texture with the base internal format specified by (or derived from) internalformat. Table 3.16 summarizes the mapping of R, G, B, A, depth, or stencil values to texture components, as a function of the base internal format of the texture image. internalformat may be specified as one of the internal format symbolic constants listed in table 3.16, as one of the sized internal format symbolic constants listed in tables 3.17-3.19, as one of the generic compressed internal format symbolic constants listed in table 3.20, or as one of the specific compressed internal format symbolic constants (if listed in table 3.20). internalformat may (for backwards compatibility with the 1.0 version of the GL) also take on the integer values 1, 2, 3, and 4, which are equivalent to symbolic constants LUMINANCE, LUMINANCE_ALPHA, RGB, and RGBA respectively. Specifying a value for internalformat that is not one of the above values generates the error INVALID_VALUE.

Table 3.16: Conversion from RGBA, depth, and stencil pixel components to internal texture, table, or filter components. See section 3.9.15 for a description of the texture components R, G, B, A, L, I, D, and S.

Textures with a base internal format of DEPTH_COMPONENT or DEPTH_STENCIL are supported by texture image specification commands only if target is TEXTURE_1D, TEXTURE_2D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, TEXTURE_RECTANGLE, TEXTURE_CUBE_MAP, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_1D_ARRAY, PROXY_TEXTURE_2D_ARRAY, PROXY_TEXTURE_RECTANGLE, or PROXY_TEXTURE_CUBE_MAP. Using these formats in conjunction with any other target will result in an INVALID_OPERATION error.

Textures with a base internal format of DEPTH_COMPONENT or DEPTH_STENCIL require either depth component data or depth/stencil component data. Textures with other base internal formats require RGBA component data. The error INVALID_OPERATION is generated if one of the base internal format and format is DEPTH_COMPONENT or DEPTH_STENCIL, and the other is neither of these values.

Textures with integer internal formats (see tables 3.17-3.18) require integer data. The error INVALID_OPERATION is generated if the internal format is integer and format is not one of the integer formats listed in table 3.6; if the internal format is not integer and format is an integer format; or if format is an integer format and type is FLOAT, HALF_FLOAT, UNSIGNED_INT_10F_11F_11F_REV, or UNSIGNED_INT_5_9_9_9_REV.

In addition to the specific compressed internal formats listed in table 3.20, the GL provides a mechanism to obtain token values for all such formats provided by extensions. The number of specific compressed internal formats supported...
by the renderer can be obtained by querying the value of \texttt{NUM_COMPRESSED_TEXTURE_FORMATS}. The set of specific compressed internal formats supported by the renderer can be obtained by querying the value of \texttt{COMPRESSED_TEXTURE_FORMATS}. The only values returned by this query are those corresponding to formats suitable for general-purpose usage. The renderer will not enumerate formats with restrictions that need to be specifically understood prior to use.

Generic compressed internal formats are never used directly as the internal formats of texture images. If \texttt{internalformat} is one of the six generic compressed internal formats, its value is replaced by the symbolic constant for a specific compressed internal format of the GL’s choosing with the same base internal format. If no specific compressed format is available, \texttt{internalformat} is instead replaced by the corresponding base internal format. If \texttt{internalformat} is given as or mapped to a specific compressed internal format, but the GL can not support images compressed in the chosen internal format for any reason (e.g., the compression format might not support 3D textures or borders), \texttt{internalformat} is replaced by the corresponding base internal format and the texture image will not be compressed by the GL.

The \textit{internal component resolution} is the number of bits allocated to each value in a texture image. If \texttt{internalformat} is specified as a base internal format, the GL stores the resulting texture with internal component resolutions of its own choosing. If a sized internal format is specified, the mapping of the R, G, B, A, depth, and stencil values to texture components is equivalent to the mapping of the corresponding base internal format’s components, as specified in table 3.16; the type (unsigned int, float, etc.) is assigned the same type specified by \texttt{internalformat}; and the memory allocation per texture component is assigned by the GL to match the allocations listed in tables 3.17-3.19 as closely as possible. (The definition of closely is left up to the implementation. However, a non-zero number of bits must be allocated for each component whose \textit{desired} allocation in tables 3.17-3.19 is non-zero, and zero bits must be allocated for all other components).

**Required Texture Formats**

Implementations are required to support at least one allocation of internal component resolution for each type (unsigned int, float, etc.) for each base internal format.

In addition, implementations are required to support the following sized and compressed internal formats. Requesting one of these sized internal formats for any texture type will allocate at least the internal component sizes, and exactly the component types shown for that format in tables 3.17-3.19:
3.9. TEXTURING

- Texture and renderbuffer color formats (see section 4.4.2).
  - RGBA32F, RGBA32I, RGBA32UI, RGBA16, RGBA16F, RGBA16I, RGBA16UI, RGBA8, RGBA8I, RGBA8UI, SRGB8_ALPHA8, and RGB10_A2.
  - R11F_G11F_B10F.
  - RG32F, RG32I, RG32UI, RG16, RG16F, RG16I, RG16UI, RG8, RG8I, and RG8UI.
  - R32F, R32I, R32UI, R16F, R16I, R16UI, R16, R8, R8I, and R8UI.
  - ALPHA8.

- Texture-only color formats:
  - RGBA16_SNORM and RGBA8_SNORM.
  - RGB32F, RGB32I, and RGB32UI.
  - RGB16_SNORM, RGB16F, RGB16I, RGB16UI, and RGB16.
  - RGB8_SNORM, RGB8, RGB8I, RGB8UI, and SRGB8.
  - RGB9_E5.
  - RG16_SNORM, RG8_SNORM, COMPRESSED_RG_RGTC2 and COMPRESSED_SIGNED_RG_RGTC2.
  - R16_SNORM, R8_SNORM, COMPRESSED_RED_RGTC1 and COMPRESSED_SIGNED_RED_RGTC1.

- Depth formats: DEPTH_COMPONENT32F, DEPTH_COMPONENT24, and DEPTH_COMPONENT16.

- Combined depth-stencil formats: DEPTH32F_STENCIL8 and DEPTH24_STENCIL8.

Encoding of Special Internal Formats

If internalformat is R11F_G11F_B10F, the red, green, and blue bits are converted to unsigned 11-bit, unsigned 11-bit, and unsigned 10-bit floating-point values as described in sections 2.1.3 and 2.1.4.

If internalformat is RGB9_E5, the red, green, and blue bits are converted to a shared exponent format according to the following procedure:

Components red, green, and blue are first clamped (in the process, mapping NaN to zero) as follows:
3.9. TEXTURING

\[
\begin{align*}
\text{red}_c &= \max(0, \min(\text{sharedexp}_{\max}, \text{red})) \\
\text{green}_c &= \max(0, \min(\text{sharedexp}_{\max}, \text{green})) \\
\text{blue}_c &= \max(0, \min(\text{sharedexp}_{\max}, \text{blue}))
\end{align*}
\]

where

\[
\text{sharedexp}_{\max} = \frac{(2^N - 1)2^{E_{\max} - B}}{2^N}.
\]

\(N\) is the number of mantissa bits per component (9), \(B\) is the exponent bias (15), and \(E_{\max}\) is the maximum allowed biased exponent value (31).

The largest clamped component, \(\text{max}_c\), is determined:

\[
\text{max}_c = \max(\text{red}_c, \text{green}_c, \text{blue}_c)
\]

A preliminary shared exponent \(\text{exp}_p\) is computed:

\[
\text{exp}_p = \max(-B - 1, \lfloor \log_2(\text{max}_c) \rfloor) + 1 + B
\]

A refined shared exponent \(\text{exp}_s\) is computed:

\[
\begin{align*}
\text{max}_s &= \left\lfloor \frac{\text{max}_c}{2^{\text{exp}_p - B - N}} + 0.5 \right\rfloor \\
\text{exp}_s &= \begin{cases} 
\text{exp}_p, & 0 \leq \text{max}_s < 2^N \\
\text{exp}_p + 1, & \text{max}_s = 2^N
\end{cases}
\end{align*}
\]

Finally, three integer values in the range 0 to \(2^N - 1\) are computed:

\[
\begin{align*}
\text{red}_s &= \left\lfloor \frac{\text{red}_c}{2^{\text{exp}_p - B - N}} + 0.5 \right\rfloor \\
\text{green}_s &= \left\lfloor \frac{\text{green}_c}{2^{\text{exp}_p - B - N}} + 0.5 \right\rfloor \\
\text{blue}_s &= \left\lfloor \frac{\text{blue}_c}{2^{\text{exp}_p - B - N}} + 0.5 \right\rfloor
\end{align*}
\]

The resulting \(\text{red}_s\), \(\text{green}_s\), \(\text{blue}_s\), and \(\text{exp}_s\) are stored in the red, green, blue, and shared bits respectively of the texture image.

An implementation accepting pixel data of type \texttt{UNSIGNED\_INT\_5\_9\_9\_9\_REV} with format \texttt{RGB} is allowed to store the components “as is” if the implementation can determine the current pixel transfer state acts as an identity transform on the components.

If a compressed internal format is specified, the mapping of the R, G, B, and A values to texture components is equivalent to the mapping of the corresponding base internal format’s components, as specified in table 3.16. The specified image is compressed using a (possibly lossy) compression algorithm chosen by the GL.

A GL implementation may vary its allocation of internal component resolution or compressed internal format based on any \texttt{TexImage3D}, \texttt{TexImage2D} (see below), or \texttt{TexImage1D} (see below) parameter (except \textit{target}), but the allocation and chosen compressed image format must not be a function of any other state and cannot be changed once they are established. In addition, the choice of a compressed...

Table 3.20: Generic and specific compressed internal formats. The specific *RGTC* formats are described in appendix C.1.
image format may not be affected by the \textit{data} parameter. Allocations must be invariant; the same allocation and compressed image format must be chosen each time a texture image is specified with the same parameter values. These allocation rules also apply to proxy textures, which are described in section 3.9.13.

The image itself (referred to by \textit{data}) is a sequence of groups of values. The first group is the lower left back corner of the texture image. Subsequent groups fill out rows of width \textit{width} from left to right; \textit{height} rows are stacked from bottom to top forming a single two-dimensional image slice; and \textit{depth} slices are stacked from back to front. When the final R, G, B, and A components have been computed for a group, they are assigned to components of a texel as described by table 3.16. Counting from zero, each resulting \textit{N}th texel is assigned internal integer coordinates \((i, j, k)\), where

\[
\begin{align*}
    i &= (N \mod \textit{width}) - w_b \\
    j &= (\lfloor N / \textit{width} \rfloor \mod \textit{height}) - h_b \\
    k &= (\lfloor N / \textit{width} \times \textit{height} \rfloor \mod \textit{depth}) - d_b
\end{align*}
\]

and \(w_b, h_b, \) and \(d_b\) are the specified border width, height, and depth. \(w_b\) and \(h_b\) are the specified \textit{border} value; \(d_b\) is the specified \textit{border} value if \textit{target} is \texttt{TEXTURE}_3D, or zero if \textit{target} is \texttt{TEXTURE}_2D\_ARRAY. Thus the last two-dimensional image slice of the three-dimensional image is indexed with the highest value of \(k\).

If the internal data type of the image array is signed or unsigned normalized fixed-point, each color component is converted using equation 2.6 or 2.4, respectively. If the internal type is floating-point or integer, components are clamped to the representable range of the corresponding internal component, but are not converted.

The \textit{level} argument to \texttt{TexImage3D} is an integer \textit{level-of-detail} number. Levels of detail are discussed below, under \texttt{Mipmapping}. The main texture image has a level of detail number of 0. If a level-of-detail less than zero is specified, the error \texttt{INVALID\_VALUE} is generated.

The \textit{border} argument to \texttt{TexImage3D} is a border width. The significance of borders is described below. The border width affects the dimensions of the texture image: let

\[
\begin{align*}
    w_s &= w_t + 2w_b \\
    h_s &= h_t + 2h_b \\
    d_s &= d_t + 2d_b
\end{align*}
\]
where $w_s$, $h_s$, and $d_s$ are the specified image width, height, and depth, and $w_t$, $h_t$, and $d_t$ are the dimensions of the texture image internal to the border. If $w_t$, $h_t$, or $d_t$ are less than zero, then the error `INVALID_VALUE` is generated.

An image with zero width, height, or depth indicates the null texture. If the null texture is specified for the level-of-detail specified by texture parameter `TEXTURE_BASE_LEVEL` (see section 3.9.6), it is as if texturing were disabled.

The maximum border width $b_t$ is 1. If $b_t$ is less than zero, or greater than $b_t$, then the error `INVALID_VALUE` is generated.

The maximum allowable width, height, or depth of a texel array for a three-dimensional texture is an implementation-dependent function of the level-of-detail and internal format of the resulting image array. It must be at least $2^{k-lod} + 2b_t$ for image arrays of level-of-detail 0 through $k$, where $k$ is the log base 2 of `MAX_-3D_TEXTURE_SIZE`, $lod$ is the level-of-detail of the image array, and $b_t$ is the maximum border width. It may be zero for image arrays of any level-of-detail greater than $k$. The error `INVALID_VALUE` is generated if the specified image is too large to be stored under any conditions.

If a pixel unpack buffer object is bound and storing texture data would access memory beyond the end of the pixel unpack buffer, an `INVALID_OPERATION` error results.

In a similar fashion, the maximum allowable width of a texel array for a one- or two-dimensional, one- or two-dimensional array, two-dimensional multisample, or two-dimensional multisample array texture, and the maximum allowable height of a two-dimensional, two-dimensional array, two-dimensional multisample, or two-dimensional multisample array texture, must be at least $2^{k-lod} + 2b_t$ for image arrays of level 0 through $k$, where $k$ is the log base 2 of `MAX_TEXTURE_SIZE`. The maximum allowable width and height of a cube map texture must be the same, and must be at least $2^{k-lod} + 2b_t$ for image arrays level 0 through $k$, where $k$ is the log base 2 of `MAX_CUBE_MAP_TEXTURE_SIZE`. The maximum number of layers for one- and two-dimensional array textures (height or depth, respectively) must be at least `MAX_ARRAY_TEXTURE_LAYERS` for all levels.

The maximum allowable width and height of a rectangular texture image must each be at least the value of the implementation-dependent constant `MAX_-RECTANGLE_TEXTURE_SIZE`.

An implementation may allow an image array of level 0 to be created only if that single image array can be supported. Additional constraints on the creation of image arrays of level 1 or greater are described in more detail in section 3.9.12.

The command

```c
void TexImage2D( enum target, int level,
                int internalformat, sizei width, sizei height,
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
3.9. TEXTURING

```c
int border, enum format, enum type, void *data);
```

is used to specify a two-dimensional texture image. `target` must be one of
`TEXTURE_2D` for a two-dimensional texture, `TEXTURE_1D_ARRAY` for a one-
dimensional array texture, `TEXTURE_RECTANGLE` for a rectangle texture, or one
of `TEXTURE_CUBE_MAP_POSITIVE_X`, `TEXTURE_CUBE_MAP_NEGATIVE_X`, `TEXTURE_CUBE_MAP_POSITIVE_Y`, `TEXTURE_CUBE_MAP_NEGATIVE_Y`, `TEXTURE_CUBE_MAP_POSITIVE_Z`, or `TEXTURE_CUBE_MAP_NEGATIVE_Z` for
a cube map texture. Additionally, `target` may be either `PROXY_TEXTURE_2D`
for a two-dimensional proxy texture, `PROXY_TEXTURE_1D_ARRAY` for a one-
dimensional proxy array texture, `PROXY_TEXTURE_RECTANGLE` for a rectangle
proxy texture, or `PROXY_TEXTURE_CUBE_MAP` for a cube map proxy texture
in the special case discussed in section 3.9.13. The other parameters match the
_corresponding parameters of `TexImage3D`.

For the purposes of decoding the texture image, `TexImage2D` is equivalent to
calling `TexImage3D` with corresponding arguments and `depth` of 1, except that

- The border depth, \(d_b\), is zero, and the `depth` of the image is always 1 regardless of the value of `border`.
- The border height, \(h_b\), is zero if `target` is `TEXTURE_1D_ARRAY`, and `border` otherwise.
- Convolution will be performed on the image (possibly changing its `width` and `height`) if `SEPARABLE_2D` or `CONVOLUTION_2D` is enabled.
- `UNPACK_SKIP.Images` is ignored.

A two-dimensional or rectangle texture consists of a single two-dimensional
texture image. A cube map texture is a set of six two-dimensional texture images.
The six cube map texture targets form a single cube map texture though each tar-
get names a distinct face of the cube map. The `TEXTURE_CUBE_MAP_*` targets
listed above update their appropriate cube map face 2D texture image. Note that
the six cube map two-dimensional image tokens such as `TEXTURE_CUBE_MAP_-
POSITIVE_X` are used when specifying, updating, or querying one of a cube map’s
six two-dimensional images, but when enabling cube map texturing or binding to
a cube map texture object (that is when the cube map is accessed as a whole as
opposed to a particular two-dimensional image), the `TEXTURE_CUBE_MAP` target
is specified.

When the `target` parameter to `TexImage2D` is one of the six cube map two-
dimensional image targets, the error `INVALID_VALUE` is generated if the `width`
and `height` parameters are not equal.
When \textit{target} is \texttt{TEXTURE\_RECTANGLE}, an \texttt{INVALID\_VALUE} error is generated if \textit{level} is non-zero.

When \textit{target} is \texttt{TEXTURE\_RECTANGLE}, an \texttt{INVALID\_VALUE} error is generated if \textit{border} is non-zero.

Finally, the command

\begin{verbatim}
void TexImage1D( enum target, int level,
                int internalformat, sizei width, int border,
                enum format, enum type, void *data );
\end{verbatim}

is used to specify a one-dimensional texture image. \textit{target} must be either \texttt{TEXTURE\_1D}, or \texttt{PROXY\_TEXTURE\_1D} in the special case discussed in section 3.9.13.

For the purposes of decoding the texture image, \texttt{TexImage1D} is equivalent to calling \texttt{TexImage2D} with corresponding arguments and \textit{height} of 1, except that

\begin{itemize}
  \item The border height and depth ($h_b$ and $d_b$) are always zero, regardless of the value of \textit{border}.
  \item Convolution will be performed on the image (possibly changing its \textit{width}) only if \texttt{CONVOLUTION\_1D} is enabled.
\end{itemize}

The image indicated to the GL by the image pointer is decoded and copied into the GL’s internal memory. This copying effectively places the decoded image inside a border of the maximum allowable width $b_t$ whether or not a border has been specified (see figure 3.10)\footnote{Figure 3.10 needs to show a three-dimensional texture image.}. If no border or a border smaller than the maximum allowable width has been specified, then the image is still stored as if it were surrounded by a border of the maximum possible width. Any excess border (which surrounds the specified image, including any border) is assigned unspecified values. A two-dimensional texture has a border only at its left, right, top, and bottom ends, and a one-dimensional texture has a border only at its left and right ends.

We shall refer to the (possibly border augmented) decoded image as the \texttt{texel array}. A three-dimensional texel array has width, height, and depth $w_s$, $h_s$, and $d_s$ as defined in equation 3.17. A two-dimensional texel array has depth $d_s = 1$, with height $h_s$ and width $w_s$ as above. A rectangular texel array must have zero border width, so $w_s$ and $h_s$ equal the specified \textit{width} and \textit{height}, respectively, while $d_s = 1$. A one-dimensional texel array has depth $d_s = 1$, height $h_s = 1$, and width $w_s$ as above.

An element $(i, j, k)$ of the texel array is called a \texttt{texel} (for a two-dimensional texture or one-dimensional array texture, $k$ is irrelevant; for a one-dimensional
3.9. TEXTURING

Figure 3.10. A texture image and the coordinates used to access it. This is a two-dimensional texture with \( n = 3 \) and \( m = 2 \). A one-dimensional texture would consist of a single horizontal strip. \( \alpha \) and \( \beta \), values used in blending adjacent texels to obtain a texture value, are also shown.

texture, \( j \) and \( k \) are both irrelevant). The texture value used in texturing a fragment is determined by that fragment’s associated \((s, t, r)\) coordinates in fixed-function fragment shading, or by sampling the texture in a shader, but may not correspond to any actual texel. See figure 3.10.

If the data argument of \texttt{TexImage1D}, \texttt{TexImage2D}, or \texttt{TexImage3D} is a null pointer (a zero-valued pointer in the C implementation), and the pixel unpack buffer object is zero, a one-, two-, or three-dimensional texel array is created with the specified \texttt{target}, \texttt{level}, \texttt{internalformat}, \texttt{border}, \texttt{width}, \texttt{height}, and \texttt{depth}, but with unspecified image contents. In this case no pixel values are accessed in client memory, and no pixel processing is performed. Errors are generated, however, exactly as though the data pointer were valid. Otherwise if the pixel unpack buffer object is non-zero, the data argument is treatedly normally to refer to the beginning of the pixel unpack buffer object’s data.
3.9. Alternate Texture Image Specification Commands

Two-dimensional and one-dimensional texture images may also be specified using image data taken directly from the framebuffer, and rectangular subregions of existing texture images may be respecified.

The command

```c
void CopyTexImage2D(enum target, int level,
    enum internalformat, int x, int y, sizei width,
   sizei height, int border);
```

defines a two-dimensional texel array in exactly the manner of `TexImage2D`, except that the image data are taken from the framebuffer rather than from client memory. Currently, `target` must be one of `TEXTURE_2D`, `TEXTURE_1D_ARRAY`, `TEXTURE_RECTANGLE`, `TEXTURE_CUBE_MAP_POSITIVE_X`, `TEXTURE_CUBE_MAP_NEGATIVE_X`, `TEXTURE_CUBE_MAP_POSITIVE_Y`, `TEXTURE_CUBE_MAP_NEGATIVE_Y`, `TEXTURE_CUBE_MAP_POSITIVE_Z`, or `TEXTURE_CUBE_MAP_NEGATIVE_Z`. `x, y, width, and height` correspond precisely to the corresponding arguments to `ReadPixels` (refer to section 4.3.2); they specify the image’s `width` and `height`, and the lower left `(x, y)` coordinates of the framebuffer region to be copied. The image is taken from the framebuffer exactly as if these arguments were passed to `ReadPixels` with argument `type` set to `COLOR`, `DEPTH`, or `DEPTH_STENCIL`, depending on `internalformat`, stopping after pixel transfer processing is complete. RGBA data is taken from the current color buffer, while depth component and stencil index data are taken from the depth and stencil buffers, respectively. The error `INVALID_OPERATION` is generated if depth component data is required and no depth buffer is present; if stencil index data is required and no stencil buffer is present; if integer RGBA data is required and the format of the current color buffer is not integer; or if floating- or fixed-point RGBA data is required and the format of the current color buffer is integer.

Subsequent processing is identical to that described for `TexImage2D`, beginning with clamping of the R, G, B, A, or depth values, and masking of the stencil index values from the resulting pixel groups. Parameters `level, internalformat, and border` are specified using the same values, with the same meanings, as the equivalent arguments of `TexImage2D`, except that `internalformat` may not be specified as 1, 2, 3, or 4. An invalid value specified for `internalformat` generates the error `INVALID_ENUM`. The constraints on `width, height, and border` are exactly those for the equivalent arguments of `TexImage2D`.

When the `target` parameter to `CopyTexImage2D` is one of the six cube map two-dimensional image targets, the error `INVALID_VALUE` is generated if the `width` and `height` parameters are not equal.
defines a one-dimensional texel array in exactly the manner of TexImage1D, except that the image data are taken from the framebuffer, rather than from client memory. Currently, target must be TEXTURE_1D. For the purposes of decoding the texture image, CopyTexImage1D is equivalent to calling CopyTexImage2D with corresponding arguments and height of 1, except that the height of the image is always 1, regardless of the value of border. level, internalformat, and border are specified using the same values, with the same meanings, as the equivalent arguments of TexImage1D, except that internalformat may not be specified as 1, 2, 3, or 4. The constraints on width and border are exactly those of the equivalent arguments of TexImage1D.

Six additional commands,

void TexSubImage3D( enum target, int level, int xoffset, int yoffset, int zoffset, sizei width, sizei height, enum format, enum type, void *data );
void TexSubImage2D( enum target, int level, int xoffset, int yoffset, sizei width, sizei height, enum format, enum type, void *data );
void TexSubImage1D( enum target, int level, int xoffset, sizei width, enum format, enum type, void *data );
void CopyTexSubImage3D( enum target, int level, int xoffset, int yoffset, int zoffset, int x, int y, sizei width, sizei height );
void CopyTexSubImage2D( enum target, int level, int xoffset, int yoffset, int x, int y, sizei width, sizei height );
void CopyTexSubImage1D( enum target, int level, int xoffset, int x, int y, sizei width );

respecify only a rectangular subregion of an existing texel array. No change is made to the internalformat, width, height, depth, or border parameters of the specified texel array, nor is any change made to texel values outside the specified subregion. Currently the target arguments of TexSubImage1D and CopyTexSubImage1D must be TEXTURE_1D, the target arguments of TexSubImage2D
and CopyTexSubImage2D must be one of TEXTURE_2D, TEXTURE_1D_ARRAY, TEXTURE_RECTANGLE, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, or TEXTURE_CUBE_MAP_NEGATIVE_Z, and the target arguments of TexSubImage3D and CopyTexSubImage3D must be TEXTURE_3D or TEXTURE_2D_ARRAY. The level parameter of each command specifies the level of the texel array that is modified. If level is less than zero or greater than the base 2 logarithm of the maximum texture width, height, or depth, the error INVALID_VALUE is generated. If target is TEXTURE_RECTANGLE and level is not zero, the error INVALID_VALUE is generated. TexSubImage3D arguments width, height, depth, format, type, and data match the corresponding arguments to TexImage3D, meaning that they are specified using the same values, and have the same meanings. Likewise, TexSubImage2D arguments width, height, format, type, and data match the corresponding arguments to TexImage2D, and TexSubImage1D arguments width, format, type, and data match the corresponding arguments to TexImage1D.

CopyTexSubImage3D and CopyTexSubImage2D arguments x, y, width, and height match the corresponding arguments to CopyTexImage2D\(^2\). CopyTexSubImage1D arguments x, y, and width match the corresponding arguments to CopyTexImage1D. Each of the TexSubImage commands interprets and processes pixel groups in exactly the manner of its TexImage counterpart, except that the assignment of R, G, B, A, depth, and stencil index pixel group values to the texture components is controlled by the internalformat of the texel array, not by an argument to the command. The same constraints and errors apply to the TexSubImage commands’ argument format and the internalformat of the texel array being re-specified as apply to the format and internalformat arguments of its TexImage counterparts.

Arguments xoffset, yoffset, and zoffset of TexSubImage3D and CopyTexSubImage3D specify the lower left texel coordinates of a width-wide by height-high by depth-deep rectangular subregion of the texel array. The depth argument associated with CopyTexSubImage3D is always 1, because framebuffer memory is two-dimensional - only a portion of a single s, t slice of a three-dimensional texture is replaced by CopyTexSubImage3D.

Negative values of xoffset, yoffset, and zoffset correspond to the coordinates of border texels, addressed as in figure 3.10. Taking \(w_s, h_s, d_s, w_b, h_b, \text{ and } d_b\) to be the specified width, height, depth, and border width, border height, and border depth of the texel array, and taking \(x, y, z, w, h, \text{ and } d\) to be the xoffset, yoffset,
3.9. TEXTURING

$zoffset$, $width$, $height$, and $depth$ argument values, any of the following relationships generates the error $INVALID_VALUE$:

\[
\begin{align*}
  x &< -w_b \\
  x + w &> w_s - w_b \\
  y &< -h_b \\
  y + h &> h_s - h_b \\
  z &< -d_b \\
  z + d &> d_s - d_b
\end{align*}
\]

Counting from zero, the $n$th pixel group is assigned to the texel with internal integer coordinates $[i, j, k]$, where

\[
\begin{align*}
  i &= x + (n \mod w) \\
  j &= y + (\left\lfloor \frac{n}{w} \right\rfloor \mod h) \\
  k &= z + \left(\left\lfloor \frac{n}{width \times height} \right\rfloor \mod d\right)
\end{align*}
\]

Arguments $xoffset$ and $yoffset$ of TexSubImage2D and CopyTexSubImage2D specify the lower left texel coordinates of a $width$-wide by $height$-high rectangular subregion of the texel array. Negative values of $xoffset$ and $yoffset$ correspond to the coordinates of border texels, addressed as in figure 3.10. Taking $w_s$, $h_s$, and $b_s$ to be the specified width, height, and border width of the texel array, and taking $x$, $y$, $w$, and $h$ to be the $xoffset$, $yoffset$, $width$, and $height$ argument values, any of the following relationships generates the error $INVALID_VALUE$:

\[
\begin{align*}
  x &< -b_s \\
  x + w &> w_s - b_s \\
  y &< -b_s \\
  y + h &> h_s - b_s
\end{align*}
\]

Counting from zero, the $n$th pixel group is assigned to the texel with internal integer coordinates $[i, j]$, where

\[
\begin{align*}
  i &= x + (n \mod w) \\
  j &= y + \left(\left\lfloor \frac{n}{w} \right\rfloor \mod h\right)
\end{align*}
\]
The \textit{xoffset} argument of \texttt{TexSubImage1D} and \texttt{CopyTexSubImage1D} specifies the left texel coordinate of a \textit{width}-wide subregion of the texel array. Negative values of \textit{xoffset} correspond to the coordinates of border texels. Taking \( w_s \) and \( b_s \) to be the specified width and border width of the texel array, and \( x \) and \( w \) to be the \textit{xoffset} and \textit{width} argument values, either of the following relationships generates the error \texttt{INVALID\_VALUE}:

\[
\begin{align*}
    x &< -b_s \\
    x + w &> w_s - b_s
\end{align*}
\]

Counting from zero, the \( n \)-th pixel group is assigned to the texel with internal integer coordinates \([i]\), where

\[
i = x + (n \mod w)
\]

Texture images with compressed internal formats may be stored in such a way that it is not possible to modify an image with subimage commands without having to decompress and recompress the texture image. Even if the image were modified in this manner, it may not be possible to preserve the contents of some of the texels outside the region being modified. To avoid these complications, the GL does not support arbitrary modifications to texture images with compressed internal formats. Calling \texttt{TexSubImage3D}, \texttt{CopyTexSubImage3D}, \texttt{TexSubImage2D}, \texttt{CopyTexSubImage2D}, \texttt{TexSubImage1D}, or \texttt{CopyTexSubImage1D} will result in an \texttt{INVALID\_OPERATION} error if \textit{xoffset}, \textit{yoffset}, or \textit{zoffset} is not equal to \(-b_s\) (border width). In addition, the contents of any texel outside the region modified by such a call are undefined. These restrictions may be relaxed for specific compressed internal formats whose images are easily modified.

If the internal format of the texture image being modified is one of the specific RGTC formats described in table 3.20, the texture is stored using one of the RGTC texture image encodings (see appendix C.1). Since RGTC images are easily edited along \( 4 \times 4 \) texel boundaries, the limitations on subimage location and size are relaxed for \texttt{TexSubImage2D}, \texttt{TexSubImage3D}, \texttt{CopyTexSubImage2D}, and \texttt{CopyTexSubImage3D}. These commands will generate an \texttt{INVALID\_OPERATION} error if one of the following conditions occurs:

- \textit{width} is not a multiple of four, \( \text{width} + \textit{xoffset} \) is not equal to the value of \texttt{TEXTURE\_WIDTH}, and either \textit{xoffset} or \textit{yoffset} is non-zero.

- \textit{height} is not a multiple of four, \( \text{height} + \textit{yoffset} \) is not equal to the value of \texttt{TEXTURE\_HEIGHT}, and either \textit{xoffset} or \textit{yoffset} is non-zero.
3.9. TEXTURING

- $xoffset$ or $yoffset$ is not a multiple of four.

The contents of any 4 × 4 block of texels of an RGTC compressed texture image that does not intersect the area being modified are preserved during valid TexSubImage* and CopyTexSubImage* calls.

Calling CopyTexSubImage3D, CopyTexImage2D, CopyTexSubImage2D, CopyTexImage1D, or CopyTexSubImage1D will result in an INVALID_FRAMEBUFFER_OPERATION error if the object bound to READ_FRAMEBUFFER_BINDING is not framebuffer complete (see section 4.4.4).

Texture Copying Feedback Loops

Calling CopyTexSubImage3D, CopyTexImage2D, CopyTexSubImage2D, CopyTexImage1D, or CopyTexSubImage1D will result in undefined behavior if the destination texture image level is also bound to to the selected read buffer (see section 4.3.2) of the read framebuffer. This situation is discussed in more detail in the description of feedback loops in section 4.4.3.

3.9.3 Compressed Texture Images

Texture images may also be specified or modified using image data already stored in a known compressed image format, such as the RGTC formats defined in appendix C, or additional formats defined by GL extensions.

The commands

```c
void CompressedTexImage1D( enum target, int level,
    enum internalformat, sizei width, int border,
    sizei imageSize, void *data );
void CompressedTexImage2D( enum target, int level,
    enum internalformat, sizei width, sizei height,
    int border, sizei imageSize, void *data );
void CompressedTexImage3D( enum target, int level,
    enum internalformat, sizei width, sizei height,
    sizei depth, int border, sizei imageSize, void *data );
```

define one-, two-, and three-dimensional texture images, respectively, with incoming data stored in a specific compressed image format. The target, level, internalformat, width, height, depth, and border parameters have the same meaning as in TexImage1D, TexImage2D, and TexImage3D, except that compressed rectangular texture formats are not supported. data refers to compressed image data stored in the specific compressed image format corresponding to internalformat.
If a pixel unpack buffer is bound (as indicated by a non-zero value of `PIXEL_UNPACK_BUFFER_BINDING`), `data` is an offset into the pixel unpack buffer and the compressed data is read from the buffer relative to this offset; otherwise, `data` is a pointer to client memory and the compressed data is read from client memory relative to the pointer.

If the `target` parameter to any of the `CompressedTexImage2D` commands is `TEXTURE_RECTANGLE` or `PROXY_TEXTURE_RECTANGLE`, the error `INVALID_ENUM` is generated.

`internalformat` must be a supported specific compressed internal format. An `INVALID_ENUM` error will be generated if any other values, including any of the generic compressed internal formats, is specified.

For all other compressed internal formats, the compressed image will be decoded according to the specification defining the `internalformat` token. Compressed texture images are treated as an array of `imageSize` ubyes relative to `data`. If a pixel unpack buffer object is bound and `data + imageSize` is greater than the size of the pixel buffer, an `INVALID_OPERATION` error results. All pixel storage and pixel transfer modes are ignored when decoding a compressed texture image. If the `imageSize` parameter is not consistent with the format, dimensions, and contents of the compressed image, an `INVALID_VALUE` error results. If the compressed image is not encoded according to the defined image format, the results of the call are undefined.

Specific compressed internal formats may impose format-specific restrictions on the use of the compressed image specification calls or parameters. For example, the compressed image format might be supported only for 2D textures, or might not allow non-zero `border` values. Any such restrictions will be documented in the extension specification defining the compressed internal format; violating these restrictions will result in an `INVALID_OPERATION` error.

Any restrictions imposed by specific compressed internal formats will be invariant, meaning that if the GL accepts and stores a texture image in compressed form, providing the same image to `CompressedTexImage1D`, `CompressedTexImage2D`, or `CompressedTexImage3D` will not result in an `INVALID_OPERATION` error if the following restrictions are satisfied:

- `data` points to a compressed texture image returned by `GetCompressedTexImage` (section 6.1.4).
- `target`, `level`, and `internalformat` match the `target`, `level` and `format` parameters provided to the `GetCompressedTexImage` call returning `data`.
- `width`, `height`, `depth`, `border`, `internalformat`, and `imageSize` match the values of `TEXTURE_WIDTH`, `TEXTURE_HEIGHT`, `TEXTURE_DEPTH`, `TEXTURE_
3.9. TEXTURING

BORDER, TEXTURE_INTERNAL_FORMAT, and TEXTURE_COMPRESSED_IMAGE_SIZE for image level level in effect at the time of the GetCompressedTexImage call returning data.

This guarantee applies not just to images returned by GetCompressedTexImage, but also to any other properly encoded compressed texture image of the same size and format.

If internalformat is one of the specific RGTC formats described in table 3.20, the compressed image data is stored using one of the RGTC compressed texture image encodings (see appendix C.1) The RGTC texture compression algorithm supports only two-dimensional images without borders. If internalformat is an RGTC format, CompressedTexImage1D will generate an INVALID_ENUM error; CompressedTexImage2D will generate an INVALID_OPERATION error if border is non-zero or target is TEXTURE_RECTANGLE; and CompressedTexImage3D will generate an INVALID_OPERATION error if border is non-zero or target is not TEXTURE_2D_ARRAY.

If the data argument of CompressedTexImage1D, CompressedTexImage2D, or CompressedTexImage3D is a null pointer (a zero-valued pointer in the C implementation), and the pixel unpack buffer object is zero, a texel array with unspecified image contents is created, just as when a null pointer is passed to TexImage1D, TexImage2D, or TexImage3D.

The commands

```c
void CompressedTexSubImage1D( enum target, int level,
   int xoffset, sizei width, enum format, sizei imageSize,
   void *data );
void CompressedTexSubImage2D( enum target, int level,
   int xoffset, int yoffset, sizei width, sizei height,
   enum format, sizei imageSize, void *data );
void CompressedTexSubImage3D( enum target, int level,
   int xoffset, int yoffset, int zoffset, sizei width,
   sizei height, sizei depth, enum format,
   sizei imageSize, void *data );
```

respecify only a rectangular region of an existing texel array, with incoming data stored in a known compressed image format. The target, level, xoffset, yoffset, zoffset, width, height, and depth parameters have the same meaning as in TexSubImage1D, TexSubImage2D, and TexSubImage3D. data points to compressed image data stored in the compressed image format corresponding to format. Using any of the generic compressed internal formats as format will result in an INVALID_ENUM error.
If the `target` parameter to any of the `CompressedTexSubImage` commands is `TEXTURE_RECTANGLE` or `PROXY_TEXTURE_RECTANGLE`, the error `INVALID_ENUM` is generated.

The image pointed to by `data` and the `imageSize` parameter are interpreted as though they were provided to `CompressedTexImage1D`, `CompressedTexImage2D`, and `CompressedTexImage3D`. These commands do not provide for image format conversion, so an `INVALID_OPERATION` error results if `format` does not match the internal format of the texture image being modified. If the `imageSize` parameter is not consistent with the format, dimensions, and contents of the compressed image (too little or too much data), an `INVALID_VALUE` error results.

As with `CompressedTexImage` calls, compressed internal formats may have additional restrictions on the use of the compressed image specification calls or parameters. Any such restrictions will be documented in the specification defining the compressed internal format; violating these restrictions will result in an `INVALID_OPERATION` error.

Any restrictions imposed by specific compressed internal formats will be invariant, meaning that if the GL accepts and stores a texture image in compressed form, providing the same image to `CompressedTexSubImage1D`, `CompressedTexSubImage2D`, `CompressedTexSubImage3D` will not result in an `INVALID_OPERATION` error if the following restrictions are satisfied:

- `data` points to a compressed texture image returned by `GetCompressedTexImage` (section 6.1.4).
- `target`, `level`, and `format` match the `target`, `level` and `format` parameters provided to the `GetCompressedTexImage` call returning `data`.
- `width`, `height`, `depth`, `format`, and `imageSize` match the values of `TEXTURE_WIDTH`, `TEXTURE_HEIGHT`, `TEXTURE_DEPTH`, `TEXTURE_INTERNAL_FORMAT`, and `TEXTURE_COMPRESSED_IMAGE_SIZE` for image level `level` in effect at the time of the `GetCompressedTexImage` call returning `data`.
- `width`, `height`, `depth`, `format` match the values of `TEXTURE_WIDTH`, `TEXTURE_HEIGHT`, `TEXTURE_DEPTH`, and `TEXTURE_INTERNAL_FORMAT` currently in effect for image level `level`.
- `xoffset`, `yoffset`, and `zoffset` are all $-b$, where $b$ is the value of `TEXTURE_BORDER` currently in effect for image level `level`.

This guarantee applies not just to images returned by `GetCompressedTexImage`, but also to any other properly encoded compressed texture image of the same size.
3.9. TEXTURING

Calling `CompressedTexSubImage3D`, `CompressedTexSubImage2D`, or `CompressedTexSubImage1D` will result in an INVALID_OPERATION error if `xoffset`, `yoffset`, or `zoffset` is not equal to \(-b\) (border width), or if `width`, `height`, and `depth` do not match the values of `TEXTURE_WIDTH`, `TEXTURE_HEIGHT`, or `TEXTURE_DEPTH`, respectively. The contents of any texel outside the region modified by the call are undefined. These restrictions may be relaxed for specific compressed internal formats whose images are easily modified.

If `internalformat` is one of the specific RGTC formats described in table 3.20, the texture is stored using one of the RGTC compressed texture image encodings (see appendix C.1). If `internalformat` is an RGTC format, `CompressedTexSubImage1D` will generate an INVALID_ENUM error; `CompressedTexSubImage2D` will generate an INVALID_OPERATION error if `border` is non-zero; and `CompressedTexSubImage3D` will generate an INVALID_OPERATION error if `border` is non-zero or `target` is not `TEXTURE_2D_ARRAY`. Since RGTC images are easily edited along \(4 \times 4\) texel boundaries, the limitations on subimage location and size are relaxed for `CompressedTexSubImage2D` and `CompressedTexSubImage3D`. These commands will result in an INVALID_OPERATION error if one of the following conditions occurs:

- `width` is not a multiple of four, and `width + xoffset` is not equal to the value of `TEXTURE_WIDTH`.
- `height` is not a multiple of four, and `height + yoffset` is not equal to the value of `TEXTURE_HEIGHT`.
- `xoffset` or `yoffset` is not a multiple of four.

The contents of any \(4 \times 4\) block of texels of an RGTC compressed texture image that does not intersect the area being modified are preserved during valid `TexSubImage*` and `CopyTexSubImage*` calls.

3.9.4 Multisample Textures

In addition to the texture types described in previous sections, two additional types of textures are supported. A multisample texture is similar to a two-dimensional or two-dimensional array texture, except it contains multiple samples per texel. Multisample textures do not have multiple image levels.

The commands

```c
void TexImage2DMultisample( enum target, sizei samples,
    int internalformat, sizei width, sizei height,
    boolean fixedsamplelocations );
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
void TexImage3DMultisample(enum target,sizei samples,
    int internalformat,sizei width,sizei height,
   sizei depth,boolean fixedsamplelocations);

establish the data storage, format, dimensions, and number of samples of a
multisample texture’s image. For TexImage2DMultisample, target must be
TEXTURE_2D_MULTISAMPLE or PROXY_TEXTURE_2D_MULTISAMPLE and for
TexImage3DMultisample target must be TEXTURE_2D_MULTISAMPLE_ARRAY
or PROXY_TEXTURE_2D_MULTISAMPLE_ARRAY. width and height are the dimen-
sions in texels of the texture.

internalformat must be color-renderable, depth-renderable, or stencil- render-
able (as defined in section 4.4.4). The error INVALID_OPERATION may be gener-
ated if any of the following are true:

- internalformat is a depth/stencil-renderable format and samples is greater
  than the value of MAX_DEPTH_TEXTURE_SAMPLES

- internalformat is a color-renderable format and samples is greater than the
  value of MAX_COLOR_TEXTURE_SAMPLES

- internalformat is a signed or unsigned integer format and samples is greater
  than the value of MAX_INTEGER_SAMPLES.

If fixedsamplelocations is TRUE, the image will use identical sample locations
and the same number of samples for all texels in the image, and the sample loca-
tions will not depend on the internalformat or size of the image. If either width or
height is greater than MAX_TEXTURE_SIZE, or if samples is greater than MAX_-SAMPLES, then the error INVALID_VALUE is generated. If the GL is unable to
create a texture level of the requested size, the error OUT_OF_MEMORY is gener-
ated.

When a multisample texture is accessed in a shader, the access takes one vector
of integers describing which texel to fetch and an integer corresponding to the
sample numbers described in section 3.3.1 describing which sample within the
texel to fetch. No standard sampling instructions are allowed on the multisample
texture targets.

3.9.5 Buffer Textures

In addition to one-, two-, and three-dimensional, one- and two-dimensional array,
and cube map textures described in previous sections, one additional type of texture
is supported. A buffer texture is similar to a one-dimensional texture. However,
3.9. TEXTURING

Unlike other texture types, the texel array is not stored as part of the texture. Instead, a buffer object is attached to a buffer texture and the texel array is taken from that buffer object’s data store. When the contents of a buffer object’s data store are modified, those changes are reflected in the contents of any buffer texture to which the buffer object is attached. Buffer textures do not have multiple image levels; only a single data store is available.

The command

```c
void TexBuffer( enum target, enum internalformat, uint buffer );
```

attaches the storage for the buffer object named `buffer` to the active buffer texture, and specifies an internal format for the texel array found in the attached buffer object. If `buffer` is zero, any buffer object attached to the buffer texture is detached, and no new buffer object is attached. If `buffer` is non-zero, but is not the name of an existing buffer object, the error `INVALID_OPERATION` is generated. `target` must be `TEXTURE_BUFFER`. `internalformat` specifies the storage format, and must be one of the sized internal formats found in table 3.21.

When a buffer object is attached to a buffer texture, the buffer object’s data store is taken as the texture’s texel array. The number of texels in the buffer texture’s texel array is given by

\[
\left\lfloor \frac{\text{buffer\_size}}{\text{components} \times \text{sizeof(base\_type)}} \right\rfloor,
\]

where `buffer\_size` is the size of the buffer object, in basic machine units and `components` and `base\_type` are the element count and base data type for elements, as specified in table 3.21. The number of texels in the texel array is then clamped to the implementation-dependent limit `MAX_TEXTURE_BUFFER_SIZE`. When a buffer texture is accessed in a shader, the results of a texel fetch are undefined if the specified texel coordinate is negative, or greater than or equal to the clamped number of texels in the texel array.

When a buffer texture is accessed in a shader, an integer is provided to indicate the texel coordinate being accessed. If no buffer object is bound to the buffer texture, the results of the texel access are undefined. Otherwise, the attached buffer object’s data store is interpreted as an array of elements of the GL data type corresponding to `internalformat`. Each texel consists of one to four elements that are mapped to texture components (R, G, B, and A). Element \( m \) of the texel numbered \( n \) is taken from element \( n \times \text{components} + m \) of the attached buffer object’s data store. Elements and texels are both numbered starting with zero. For texture formats with signed or unsigned normalized fixed-point components, the extracted
values are converted to floating-point using equations 2.1 or 2.3, respectively. The components of the texture are then converted to an (R,G,B,A) vector according to table 3.21, and returned to the shader as a four-component result vector with components of the appropriate data type for the texture’s internal format. The base data type, component count, normalized component information, and mapping of data store elements to texture components is specified in table 3.21.

In addition to attaching buffer objects to textures, buffer objects can be bound to the buffer object target named TEXTURE_BUFFER, in order to specify, modify, or read the buffer object’s data store. The buffer object bound to TEXTURE_BUFFER has no effect on rendering. A buffer object is bound to TEXTURE_BUFFER by calling BindBuffer with target set to TEXTURE_BUFFER, as described in section 2.9.

3.9.6 Texture Parameters

Various parameters control how the texel array is treated when specified or changed, and when applied to a fragment. Each parameter is set by calling

```c
void TexParameter(if)( enum target, enum pname, T param );
void TexParameter(if)v( enum target, enum pname,
    T *params );
void TexParameterI(ui)v( enum target, enum pname,
    T *params );
```

`target` is the target, either TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, TEXTURE_RECTANGLE, or TEXTURE_CUBE_MAP. `pname` is a symbolic constant indicating the parameter to be set; the possible constants and corresponding parameters are summarized in table 3.22. In the first form of the command, `param` is a value to which to set a single-valued parameter; in the remaining forms, `params` is an array of parameters whose type depends on the parameter being set.

If the value for TEXTURE_PRIORITY is specified with TexParameteri or TexParameteriv, it is converted to floating-point using equation 2.2, followed by clamping the value to lie in [0, 1].

If the values for TEXTURE_BORDER_COLOR are specified with TexParameteri or TexParameteriv, the values are unmodified and stored with an internal data type of integer. If specified with TexParameteriv, they are converted to floating-point using equation 2.2. Otherwise the values are unmodified and stored as floating-point.

In the remainder of section 3.9, denote by `lod_min`, `lod_max`, `level_base`, and `level_max` the values of the texture parameters TEXTURE_MIN_LOD, TEXTURE_MAX_LOD, TEXTURE_BASE_LEVEL, and TEXTURE_MAX_LEVEL respectively.
### Table 3.21: Internal formats for buffer textures.

For each format, the data type of each element is indicated in the “Base Type” column and the element count is in the “Components” column. The “Norm” column indicates whether components should be treated as normalized floating-point values. The “Component 0, 1, 2, and 3” columns indicate the mapping of each element of a texel to texture components.

</tbody>
</table>

Table 3.22: Texture parameters and their values.
Texture parameters for a cube map texture apply to the cube map as a whole; the six distinct two-dimensional texture images use the texture parameters of the cube map itself.

If the value of texture parameter `GENERATE_MIPMAP` is `TRUE`, specifying or changing texel arrays may have side effects, which are discussed in the Automatic Mipmap Generation discussion of section 3.9.9.

When `target` is `TEXTURE_RECTANGLE`, certain texture parameter values may not be specified. In this case, the error `INVALID_ENUM` is generated if the `TEXTURE_WRAP_S`, `TEXTURE_WRAP_T`, or `TEXTURE_WRAP_R` parameter is set to `REPEAT` or `MIRRORED_REPEAT`. The error `INVALID_ENUM` is generated if `TEXTURE_MIN_FILTER` is set to a value other than `NEAREST` or `LINEAR` (no mipmap filtering is permitted). The error `INVALID_ENUM` is generated if `TEXTURE_BASE_LEVEL` is set to any value other than zero.

### 3.9.7 Depth Component Textures

Depth textures and the depth components of depth/stencil textures can be treated as `RED`, `LUMINANCE`, `INTENSITY` or `ALPHA` textures during texture filtering and application (see section 3.9.16). The initial state for depth and depth/stencil textures treats them as `LUMINANCE` textures except in a forward-compatible context, where the initial state instead treats them as `RED` textures.

### 3.9.8 Cube Map Texture Selection

When cube map texturing is enabled, the \((s\ t\ r)\) texture coordinates are treated as a direction vector \((r_x\ r_y\ r_z)\) emanating from the center of a cube (the \(q\) coordinate can be ignored, since it merely scales the vector without affecting the direction.) At texture application time, the interpolated per-fragment direction vector selects one of the cube map face’s two-dimensional images based on the largest magnitude coordinate direction (the major axis direction). If two or more coordinates have the identical magnitude, the implementation may define the rule to disambiguate this situation. The rule must be deterministic and depend only on \((r_x\ r_y\ r_z)\). The target column in table 3.23 explains how the major axis direction maps to the two-dimensional image of a particular cube map target.

Using the \(s_c, t_c,\) and \(m_a\) determined by the major axis direction as specified in table 3.23, an updated \((s\ t)\) is calculated as follows:

\[
s = \frac{1}{2} \left( \frac{s_c}{|m_a|} + 1 \right)
\]
### 3.9. TEXTURING

</tbody>
</table>

The equation for texturing is:

$$t = \frac{1}{2} \left( \frac{t_c}{|m_a|} + 1 \right)$$

#### Seamless Cube Map Filtering

Seamless cube map filtering is enabled or disabled by calling `Enable` or `Disable`, respectively, with the symbolic constant `TEXTURE_CUBE_MAP_SEAMLESS`.

When seamless cube map filtering is disabled, the new $(s \ t)$ is used to find a texture value in the determined face’s two-dimensional image using the rules given in sections 3.9.9 through 3.9.10.

When seamless cube map filtering is enabled, the rules for texel selection in sections 3.9.9 through 3.9.10 are modified so that texture wrap modes are ignored. Instead,

- If **NEAREST** filtering is done within a mipmap, always apply wrap mode `CLAMP_TO_EDGE`.
- If **LINEAR** filtering is done within a mipmap, always apply wrap mode `CLAMP_TO_BORDER`. Then,
  - If a texture sample location would lie in the texture border in either $u$ or $v$, instead select the corresponding texel from the appropriate neighboring face.
  - If a texture sample location would lie in the texture border in both $u$ and $v$ (in one of the corners of the cube), there is no unique neighboring face from which to extract one texel. The recommended method to generate this texel is to average the values of the three available samples. However, implementations are free to construct this fourth texel.
in another way, so long as, when the three available samples have the same value, this texel also has that value.

The required state is one bit indicating whether seamless cube map filtering is enabled or disabled. Initially, it is disabled.

### 3.9.9 Texture Minification

Applying a texture to a primitive implies a mapping from texture image space to framebuffer image space. In general, this mapping involves a reconstruction of the sampled texture image, followed by a homogeneous warping implied by the mapping to framebuffer space, then a filtering, followed finally by a resampling of the filtered, warped, reconstructed image before applying it to a fragment. In the GL this mapping is approximated by one of two simple filtering schemes. One of these schemes is selected based on whether the mapping from texture space to framebuffer space is deemed to magnify or minify the texture image.

#### Scale Factor and Level of Detail

The choice is governed by a scale factor $\rho(x, y)$ and the level-of-detail parameter $\lambda(x, y)$, defined as

$$\lambda_{\text{base}}(x, y) = \log_2[\rho(x, y)]$$

(3.18)

$$\lambda'(x, y) = \lambda_{\text{base}}(x, y) + \text{clamp}(\text{bias}_{\text{texobj}} + \text{bias}_{\text{texunit}} + \text{bias}_{\text{shader}})$$

(3.19)

$$\lambda = \begin{cases} 
\text{lod}_{\text{max}}, & \lambda' > \text{lod}_{\text{max}} \\
\lambda', & \text{lod}_{\text{min}} \leq \lambda' \leq \text{lod}_{\text{max}} \\
\text{lod}_{\text{min}}, & \lambda' < \text{lod}_{\text{min}} \\
\text{undefined}, & \text{lod}_{\text{min}} > \text{lod}_{\text{max}}
\end{cases}$$

(3.20)

$bias_{\text{texobj}}$ is the value of \text{TEXTURE\_LOD\_BIAS} for the bound texture object (as described in section 3.9.6). $bias_{\text{texunit}}$ is the value of \text{TEXTURE\_LOD\_BIAS} for the current texture unit (as described in section 3.9.15). $bias_{\text{shader}}$ is the value of the optional bias parameter in the texture lookup functions available to fragment shaders. If the texture access is performed in a fragment shader without a provided bias, or outside a fragment shader, then $bias_{\text{shader}}$ is zero. The sum of these values is clamped to the range $[-bias_{\text{max}}, bias_{\text{max}}]$ where $bias_{\text{max}}$ is the value of the implementation defined constant \text{MAX\_TEXTURE\_LOD\_BIAS}.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
If \( \lambda(x, y) \) is less than or equal to the constant \( c \) (see section 3.9.10) the texture is said to be magnified; if it is greater, the texture is minified. Sampling of minified textures is described in the remainder of this section, while sampling of magnified textures is described in section 3.9.10.

The initial values of \( \text{lod}_{\text{min}} \) and \( \text{lod}_{\text{max}} \) are chosen so as to never clamp the normal range of \( \lambda \). They may be respecified for a specific texture by calling \text{TexParameter} with \( \text{pname} \) set to \( \text{TEXTURE\_MIN\_LOD} \) or \( \text{TEXTURE\_MAX\_LOD} \) respectively.

Let \( s(x, y) \) be the function that associates an \( s \) texture coordinate with each set of window coordinates \((x, y)\) that lie within a primitive; define \( t(x, y) \) and \( r(x, y) \) analogously. Let

\[
\begin{align*}
  u(x, y) &= \begin{cases} 
  s(x, y) + \delta_u, & \text{rectangular texture} \\
  w_t \times s(x, y) + \delta_u, & \text{otherwise}
  \end{cases} \\
  v(x, y) &= \begin{cases} 
  t(x, y) + \delta_v, & \text{rectangular texture} \\
  h_t \times t(x, y) + \delta_v, & \text{otherwise}
  \end{cases} \\
  w(x, y) &= d_t \times r(x, y) + \delta_w
\end{align*}
\]

where \( w_t, h_t, \) and \( d_t \) are as defined by equation 3.17 with \( w_s, h_s, \) and \( d_s \) equal to the width, height, and depth of the image array whose level is \( \text{level}_{\text{base}} \). For a one-dimensional or one-dimensional array texture, define \( v(x, y) = 0 \) and \( w(x, y) = 0 \); for a two-dimensional, two-dimensional array, rectangular, or cube map texture, define \( w(x, y) = 0 \).

\((\delta_u, \delta_v, \delta_w)\) are the texel offsets specified in the OpenGL Shading Language texture lookup functions that support offsets. If the texture function used does not support offsets, or for fixed-function texture accesses, all three shader offsets are taken to be zero. If any of the offset values are outside the range of the implementation-defined values \( \text{MIN\_PROGRAM\_TEXEL\_OFFSET} \) and \( \text{MAX\_PROGRAM\_TEXEL\_OFFSET} \), results of the texture lookup are undefined.

For a polygon, or for a point sprite with texture coordinate replacement enabled, \( \rho \) is given at a fragment with window coordinates \((x, y)\) by

\[
\rho = \max \left\{ \sqrt{\frac{\partial u}{\partial x}^2 + \frac{\partial v}{\partial x}^2 + \frac{\partial w}{\partial x}^2}, \sqrt{\frac{\partial u}{\partial y}^2 + \frac{\partial v}{\partial y}^2 + \frac{\partial w}{\partial y}^2} \right\}
\]

(3.22)

where \( \partial u/\partial x \) indicates the derivative of \( u \) with respect to window \( x \), and similarly for the other derivatives.
For a line, the formula is

\[
\rho = \sqrt{\left( \frac{\partial u}{\partial x} \Delta x + \frac{\partial u}{\partial y} \Delta y \right)^2 + \left( \frac{\partial v}{\partial x} \Delta x + \frac{\partial v}{\partial y} \Delta y \right)^2 + \left( \frac{\partial w}{\partial x} \Delta x + \frac{\partial w}{\partial y} \Delta y \right)^2} / l,
\]

(3.23)

where \( \Delta x = x_2 - x_1 \) and \( \Delta y = y_2 - y_1 \) with \((x_1, y_1)\) and \((x_2, y_2)\) being the segment’s window coordinate endpoints and \( l = \sqrt{\Delta x^2 + \Delta y^2} \).

For a point, point sprite without texture coordinate replacement enabled, pixel rectangle, or bitmap, \( \rho = 1 \).

While it is generally agreed that equations 3.22 and 3.23 give the best results when texturing, they are often impractical to implement. Therefore, an implementation may approximate the ideal \( \rho \) with a function \( f(x, y) \) subject to these conditions:

1. \( f(x, y) \) is continuous and monotonically increasing in each of \( |\partial u/\partial x| \), \( |\partial u/\partial y| \), \( |\partial v/\partial x| \), \( |\partial v/\partial y| \), \( |\partial w/\partial x| \), and \( |\partial w/\partial y| \)

2. Let

\[
\begin{align*}
  m_u &= \max \left\{ \left| \frac{\partial u}{\partial x} \right|, \left| \frac{\partial u}{\partial y} \right| \right\} \\
  m_v &= \max \left\{ \left| \frac{\partial v}{\partial x} \right|, \left| \frac{\partial v}{\partial y} \right| \right\} \\
  m_w &= \max \left\{ \left| \frac{\partial w}{\partial x} \right|, \left| \frac{\partial w}{\partial y} \right| \right\}
\end{align*}
\]

Then \( \max\{m_u, m_v, m_w\} \leq f(x, y) \leq m_u + m_v + m_w \).

**Coordinate Wrapping and Texel Selection**

After generating \( u(x, y) \), \( v(x, y) \), and \( w(x, y) \), they may be clamped and wrapped before sampling the texture, depending on the corresponding texture wrap modes.

Let
3.9. TEXTURING

\[
u'(x, y) = \begin{cases} 
\text{clamp}(u(x, y), 0, w_t), & \text{TEXTURE_WRAP_S is CLAMP} \\
u(x, y), & \text{otherwise}
\end{cases}
\]

\[
v'(x, y) = \begin{cases} 
\text{clamp}(v(x, y), 0, h_t), & \text{TEXTURE_WRAP_T is CLAMP} \\
v(x, y), & \text{otherwise}
\end{cases}
\]

\[
w'(x, y) = \begin{cases} 
\text{clamp}(w(x, y), 0, d_t), & \text{TEXTURE_WRAP_R is CLAMP} \\
w(x, y), & \text{otherwise}
\end{cases}
\]

where \(\text{clamp}(a, b, c)\) returns \(b\) if \(a < b\), \(c\) if \(a > c\), and \(a\) otherwise.

The value assigned to \text{TEXTURE_MIN_FILTER} is used to determine how the texture value for a fragment is selected.

When the value of \text{TEXTURE_MIN_FILTER} is \text{NEAREST}, the texel in the image array of level \text{level_base} that is nearest (in Manhattan distance) to \((u', v', w')\) is obtained. Let \((i, j, k)\) be integers such that

\[
i = \text{wrap}(\lfloor u'(x, y) \rfloor)
\]

\[
j = \text{wrap}(\lfloor v'(x, y) \rfloor)
\]

\[
k = \text{wrap}(\lfloor w'(x, y) \rfloor)
\]

and the value returned by \(\text{wrap}()\) is defined in table 3.24. For a three-dimensional texture, the texel at location \((i, j, k)\) becomes the texture value. For two-dimensional, two-dimensional array, rectangular, or cube map textures, \(k\) is irrelevant, and the texel at location \((i, j)\) becomes the texture value. For one-dimensional texture or one-dimensional array textures, \(j\) and \(k\) are irrelevant, and the texel at location \(i\) becomes the texture value.

For one- and two-dimensional array textures, the texel is obtained from image layer \(l\), where

\[
l = \begin{cases} 
\text{clamp}([ t + 0.5], 0, h_t - 1), & \text{for one-dimensional array textures} \\
\text{clamp}([ r + 0.5], 0, d_t - 1), & \text{for two-dimensional array textures}
\end{cases}
\]

If the selected \((i, j, k), (i, j)\), or \(i\) location refers to a border texel that satisfies any of the conditions

\[
i < -b_s \\
\geq w_t + b_s \\

j < -b_s \\
\geq h_t + b_s \\

k < -b_s \\
\geq d_t + b_s
\]
3.9. TEXTURING

<table>
<thead>
<tr>
<th>Wrap mode</th>
<th>Result of ( \text{wrap}(\text{coord}) )</th>
</tr>
</thead>
</table>
| CLAMP              | \[
\begin{align*}
\text{clamp}(\text{coord}, 0, \text{size} - 1), & \quad \text{for NEAREST filtering} \\
\text{clamp}(\text{coord}, -1, \text{size}), & \quad \text{for LINEAR filtering}
\end{align*}
\] |
| CLAMP_TO_EDGE      | \( \text{clamp}(\text{coord}, 0, \text{size} - 1) \)                                                      |
| CLAMP_TO_BORDER    | \( \text{clamp}(\text{coord}, -1, \text{size}) \)                                                      |
| REPEAT             | \( \text{fmod}(\text{coord}, \text{size}) \)                                                           |
| MIRRORED_REPEAT    | \( (\text{size} - 1) - \text{mirror}(\text{fmod}(\text{coord}, 2 \times \text{size}) - \text{size}) \) |

Table 3.24: Texel location wrap mode application. \( \text{fmod}(a, b) \) returns \( a - b \times \left\lfloor \frac{a}{b} \right\rfloor \). \( \text{mirror}(a) \) returns \( a \) if \( a \geq 0 \), and \( -(1 + a) \) otherwise. The values of \( \text{mode} \) and \( \text{size} \) are TEXTURE_WRAP_S and \( w_t \), TEXTURE_WRAP_T and \( h_t \), and TEXTURE_WRAP_R and \( d_t \) when wrapping \( i \), \( j \), or \( k \) coordinates, respectively.

then the border values defined by TEXTURE_BORDER_COLOR are used in place of the non-existent texel. If the texture contains color components, the values of TEXTURE_BORDER_COLOR are interpreted as an RGBA color to match the texture’s internal format in a manner consistent with table 3.16. The internal data type of the border values must be consistent with the type returned by the texture as described in section 3.9, or the result is undefined. Border values are clamped before they are used, according to the format in which texture components are stored. For signed and unsigned normalized fixed-point formats, border values are clamped to \([-1, 1]\) and \([0, 1]\), respectively. For floating-point and integer formats, border values are clamped to the representable range of the format. If the texture contains depth components, the first component of TEXTURE_BORDER_COLOR is interpreted as a depth value.

When the value of TEXTURE_MIN_FILTER is LINEAR, a \( 2 \times 2 \times 2 \) cube of texels in the image array of level \( \text{level}_{\text{base}} \) is selected. Let
3.9. TEXTURING

\[
i_0 = \text{wrap}(\lfloor u' - 0.5 \rfloor)
\]
\[
j_0 = \text{wrap}(\lfloor v' - 0.5 \rfloor)
\]
\[
k_0 = \text{wrap}(\lfloor w' - 0.5 \rfloor)
\]
\[
i_1 = \text{wrap}(\lfloor u' - 0.5 \rfloor + 1)
\]
\[
j_1 = \text{wrap}(\lfloor v' - 0.5 \rfloor + 1)
\]
\[
k_1 = \text{wrap}(\lfloor w' - 0.5 \rfloor + 1)
\]
\[
\alpha = \frac{u' - 0.5}{\text{frac}(u'-0.5)}
\]
\[
\beta = \frac{v' - 0.5}{\text{frac}(v'-0.5)}
\]
\[
\gamma = \frac{w' - 0.5}{\text{frac}(w'-0.5)}
\]

where \(\text{frac}(x)\) denotes the fractional part of \(x\).

For a three-dimensional texture, the texture value \(\tau\) is found as

\[
\tau = (1 - \alpha)(1 - \beta)(1 - \gamma)\tau_{i_0j_0k_0} + \alpha(1 - \beta)(1 - \gamma)\tau_{i_1j_0k_0}
\]
\[
+ (1 - \alpha)\beta(1 - \gamma)\tau_{i_0j_1k_0} + \alpha\beta(1 - \gamma)\tau_{i_1j_1k_0}
\]
\[
+ (1 - \alpha)(1 - \beta)\gamma\tau_{i_0j_0k_1} + \alpha(1 - \beta)\gamma\tau_{i_1j_0k_1}
\]
\[
+ (1 - \alpha)\beta\gamma\tau_{i_0j_1k_1} + \alpha\beta\gamma\tau_{i_1j_1k_1}
\]

where \(\tau_{ijk}\) is the texel at location \((i, j, k)\) in the three-dimensional texture image.

For a two-dimensional, two-dimensional array, rectangular, or cube map texture,

\[
\tau = (1 - \alpha)(1 - \beta)\tau_{i,j_0} + \alpha(1 - \beta)\tau_{i,j_1}
\]

where \(\tau_{ij}\) is the texel at location \((i, j)\) in the two-dimensional texture image. For two-dimensional array textures, all texels are obtained from layer \(l\), where

\[
l = \text{clamp}([r + 0.5], 0, d_t - 1).
\]

And for a one-dimensional or one-dimensional array texture,

\[
\tau = (1 - \alpha)\tau_i + \alpha\tau_{i+1}
\]

where \(\tau_i\) is the texel at location \(i\) in the one-dimensional texture. For one-dimensional array textures, both texels are obtained from layer \(l\), where
3.9. TEXTURING

\[ l = \text{clamp}(\lfloor t + 0.5 \rfloor, 0, h_t - 1). \]

For any texel in the equation above that refers to a border texel outside the defined range of the image, the texel value is taken from the texture border color as with \texttt{NEAREST} filtering.

Rendering Feedback Loops

If all of the following conditions are satisfied, then the value of the selected \( \tau_{ijk} \), \( \tau_{ij} \), or \( \tau_i \) in the above equations is undefined instead of referring to the value of the texel at location \((i,j,k), (i,j), \) or \((i)\) respectively. This situation is discussed in more detail in the description of feedback loops in section 4.4.3.

- The current \texttt{DRAW_FRAMEBUFFER_BINDING} names a framebuffer object \( F \).
- The texture is attached to one of the attachment points, \( A \), of framebuffer object \( F \).
- The value of \texttt{TEXTURE_MIN_FILTER} is \texttt{NEAREST} or \texttt{LINEAR}, and the value of \texttt{FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL} for attachment point \( A \) is equal to the value of \texttt{TEXTURE_BASE_LEVEL} -or-

The value of \texttt{TEXTURE_MIN_FILTER} is \texttt{NEAREST_MIPMAP_NEAREST}, \texttt{NEAREST_MIPMAP_LINEAR}, \texttt{LINEAR_MIPMAP_NEAREST}, or \texttt{LINEAR_MIPMAP_LINEAR}, and the value of \texttt{FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL} for attachment point \( A \) is within the inclusive range from \texttt{TEXTURE_BASE_LEVEL} to \( q \).

Mipmapping

\texttt{TEXTURE_MIN_FILTER} values \texttt{NEAREST_MIPMAP_NEAREST}, \texttt{NEAREST_MIPMAP_LINEAR}, \texttt{LINEAR_MIPMAP_NEAREST}, \texttt{and} \texttt{LINEAR_MIPMAP_LINEAR} each require the use of a \textit{mipmap}. Rectangular textures do not support mipmapping (it is an error to specify a minification filter that requires mipmapping). A mipmap is an ordered set of arrays representing the same image; each array has a resolution lower than the previous one. If the image array of level \texttt{level_base} (excluding its border) has dimensions \( w_t \times h_t \times d_t \), then there are \( \lceil \log_2(\text{maxsize}) \rceil + 1 \) levels in the mipmap.
3.9. TEXTURING

\[
\text{maxsize} = \begin{cases} 
  w_t, & \text{for 1D and 1D array textures} \\
  \max(w_t, h_t), & \text{for 2D, 2D array, and cube map textures} \\
  \max(w_t, h_t, d_t), & \text{for 3D textures}
\end{cases}
\]

Numbering the levels such that level \( \text{level}_{\text{base}} \) is the 0th level, the \( i \)th array has dimensions

\[
\max(1, \left\lfloor \frac{w_t}{w_d} \right\rfloor) \times \max(1, \left\lfloor \frac{h_t}{h_d} \right\rfloor) \times \max(1, \left\lfloor \frac{d_t}{d_d} \right\rfloor)
\]

where

\[
w_d = 2^i \\
h_d = \begin{cases} 
  1, & \text{for 1D and 1D array textures} \\
  2^i, & \text{otherwise}
\end{cases} \\
d_d = \begin{cases} 
  2^i, & \text{for 3D textures} \\
  1, & \text{otherwise}
\end{cases}
\]

until the last array is reached with dimension \( 1 \times 1 \times 1 \).

Each array in a mipmap is defined using \texttt{TexImage3D}, \texttt{TexImage2D}, \texttt{CopyTexImage2D}, \texttt{TexImage1D}, or \texttt{CopyTexImage1D}; the array being set is indicated with the level-of-detail argument \texttt{level}. Level-of-detail numbers proceed from \( \text{level}_{\text{base}} \) for the original texel array through \( p = \left\lfloor \log_2(\text{maxsize}) \right\rfloor + \text{level}_{\text{base}} \) with each unit increase indicating an array of half the dimensions of the previous one (rounded down to the next integer if fractional) as already described. All arrays from \( \text{level}_{\text{base}} \) through \( q = \min\{p, \text{level}_{\text{max}}\} \) must be defined, as discussed in section 3.9.12.

The values of \texttt{LEVEL}_{\text{base}} and \texttt{LEVEL}_{\text{max}} may be respecified for a specific texture by calling \texttt{TexParameter[if]} with \texttt{pname} set to \texttt{TEXTURE\_BASE\_LEVEL} or \texttt{TEXTURE\_MAX\_LEVEL} respectively.

The error \texttt{INVALID\_VALUE} is generated if either value is negative.

The mipmap is used in conjunction with the level of detail to approximate the application of an appropriately filtered texture to a fragment. Let \( c \) be the value of \( \lambda \) at which the transition from minification to magnification occurs (since this discussion pertains to minification, we are concerned only with values of \( \lambda \) where \( \lambda > c \)).
For mipmap filters NEAREST_MIPMAP_NEAREST and LINEAR_MIPMAP_NEAREST, the $d$th mipmap array is selected, where

\[
d = \begin{cases} 
  \text{level}_\text{base}, & \lambda \leq \frac{1}{2} \\
  \lfloor \text{level}_\text{base} + \lambda + \frac{1}{2} \rfloor - 1, & \lambda > \frac{1}{2}, \text{level}_\text{base} + \lambda \leq q + \frac{1}{2} \\
  q, & \lambda > \frac{1}{2}, \text{level}_\text{base} + \lambda > q + \frac{1}{2}
\end{cases}
\quad (3.25)
\]

The rules for NEAREST or LINEAR filtering are then applied to the selected array. Specifically, the coordinate $(u, v, w)$ is computed as in equation 3.21, with $w_s, h_s, \text{and } d_s$ equal to the width, height, and depth of the image array whose level is $d$.

For mipmap filters NEAREST_MIPMAP_LINEAR and LINEAR_MIPMAP_LINEAR, the level $d_1$ and $d_2$ mipmap arrays are selected, where

\[
d_1 = \begin{cases} 
  q, & \text{level}_\text{base} + \lambda \geq q \\
  \lfloor \text{level}_\text{base} + \lambda \rfloor, & \text{otherwise}
\end{cases}
\quad (3.26)
\]

\[
d_2 = \begin{cases} 
  q, & \text{level}_\text{base} + \lambda \geq q \\
  d_1 + 1, & \text{otherwise}
\end{cases}
\quad (3.27)
\]

The rules for NEAREST or LINEAR filtering are then applied to each of the selected arrays, yielding two corresponding texture values $\tau_1$ and $\tau_2$. Specifically, for level $d_1$, the coordinate $(u, v, w)$ is computed as in equation 3.21, with $w_s, h_s, \text{and } d_s$ equal to the width, height, and depth of the image array whose level is $d_1$.

For level $d_2$ the coordinate $(u', v', w')$ is computed as in equation 3.21, with $w_s, h_s, \text{and } d_s$ equal to the width, height, and depth of the image array whose level is $d_2$.

The final texture value is then found as

\[
\tau = [1 - \text{frac}(\lambda)]\tau_1 + \text{frac}(\lambda)\tau_2.
\]

**Manual Mipmap Generation**

Mipmaps can be generated manually with the command

```
void GenerateMipmap(enum target);
```

where `target` is one of TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, or TEXTURE_CUBE_MAP. Mipmap generation
affects the texture image attached to target. For cube map textures, an INVALIDOperationException error is generated if the texture bound to target is not cube complete, as defined in section 3.9.12.

Mipmap generation replaces texel array levels levelbase + 1 through q with arrays derived from the levelbase array, regardless of their previous contents. All other mipmap arrays, including the levelbase array, are left unchanged by this computation.

The internal formats and border widths of the derived mipmap arrays all match those of the levelbase array, and the dimensions of the derived arrays follow the requirements described in section 3.9.12.

The contents of the derived arrays are computed by repeated, filtered reduction of the levelbase array. For one- and two-dimensional array textures, each layer is filtered independently. No particular filter algorithm is required, though a box filter is recommended as the default filter. In some implementations, filter quality may be affected by hints (section 5.7).

Automatic Mipmap Generation

If the value of texture parameter GENERATE_MIPMAP is TRUE, and a change is made to the interior or border texels of the levelbase array of a mipmap by one of the texture image specification operations defined in sections 3.9.1 through 3.9.3, then a \[^3\] complete set of mipmap arrays (as defined in section 3.9.12) will be computed. Array levels levelbase + 1 through p are replaced with arrays derived from the modified levelbase array, as described above for Manual Mipmap Generation. All other mipmap arrays, including the levelbase array, are left unchanged by this computation. For arrays in the range levelbase + 1 through q, inclusive, automatic and manual mipmap generation generate the same derived arrays, given identical levelbase arrays.

Automatic mipmap generation is available only for non-proxy texture image targets.

3.9.10 Texture Magnification

When \( \lambda \) indicates magnification, the value assigned to TEXTURE_MAG_FILTER determines how the texture value is obtained. There are two possible values for TEXTURE_MAG_FILTER: NEAREST and LINEAR. NEAREST behaves exactly as NEAREST for TEXTURE_MIN_FILTER and LINEAR behaves exactly as LINEAR for

[^3]: Automatic mipmap generation is not performed for changes resulting from rendering operations targeting a texel array bound as a color buffer of a framebuffer object.
TEXTURE_MIN_FILTER as described in section 3.9.9, including the texture coordinate wrap modes specified in table 3.24. The level-of-detail \textit{level\textsubscript{base}} texel array is always used for magnification.

Implementations may either unconditionally assume \(c = 0\) for the minification vs. magnification switch-over point, or may choose to make \(c\) depend on the combination of minification and magnification modes as follows: if the magnification filter is given by \texttt{LINEAR} and the minification filter is given by \texttt{NEAREST\_MIPMAP\_NEAREST} or \texttt{NEAREST\_MIPMAP\_LINEAR}, then \(c = 0.5\). This is done to ensure that a minified texture does not appear “sharper” than a magnified texture. Otherwise \(c = 0\).

3.9.11 Combined Depth/Stencil Textures

If the texture image has a base internal format of \texttt{DEPTH\_STENCIL}, then the stencil index texture component is ignored. The texture value \(\tau\) does not include a stencil index component, but includes only the depth component.

3.9.12 Texture Completeness

A texture is said to be \textit{complete} if all the image arrays and texture parameters required to utilize the texture for texture application are consistently defined. The definition of completeness varies depending on texture dimensionality and type.

For one-, two-, and three-dimensional and one-and two-dimensional array textures, a texture is \textit{mipmap complete} if all of the following conditions hold true:

- The set of mipmap arrays \textit{level\textsubscript{base}} through \(q\) (where \(q\) is defined in the Mipmapping discussion of section 3.9.9) were each specified with the same internal format.
- The border widths of each array are the same.
- The dimensions of the arrays follow the sequence described in the Mipmapping discussion of section 3.9.9.
- \(\textit{level\textsubscript{base}} \leq \textit{level\textsubscript{max}}\)

Array levels \(k\) where \(k < \textit{level\textsubscript{base}}\) or \(k > q\) are insignificant to the definition of completeness.

A cube map texture is mipmap complete if each of the six texture images, considered individually, is mipmap complete. Additionally, a cube map texture is \textit{cube complete} if the following conditions all hold true:
The $level_{base}$ arrays of each of the six texture images making up the cube map have identical, positive, and square dimensions.

- The $level_{base}$ arrays were each specified with the same internal format.
- The $level_{base}$ arrays each have the same border width.

Using the preceding definitions, a texture is complete unless any of the following conditions hold true:

- Any dimension of the $level_{base}$ array is not positive. For a rectangular or multisample texture, $level_{base}$ is always zero.
- The texture is a cube map texture, and is not cube complete.
- The minification filter requires a mipmap (is neither NEAREST nor LINEAR), and the texture is not mipmap complete.
- The internal format of the texture arrays is integer (see tables 3.17-3.18), and either the magnification filter is not NEAREST, or the minification filter is neither NEAREST nor NEAREST_MIPMAP_NEAREST.

Effects of Completeness on Texture Application

Texture lookup and texture fetch operations performed in vertex, geometry, and fragment shaders are affected by completeness of the texture being sampled as described in sections 2.14.4 and 3.12.2.

For fixed-function texture access, if texturing is enabled for a texture unit at the time a primitive is rasterized, and if the texture image bound to the enabled texture target is not complete, then it is as if texture mapping were disabled for that texture unit.

Effects of Completeness on Texture Image Specification

An implementation may allow a texture image array of level 1 or greater to be created only if a mipmap complete set of image arrays consistent with the requested array can be supported with $level_{base} = 0$ and $level_{max} = 1000$. 
3.9. TEXTURING

3.9.13 Texture State and Proxy State

The state necessary for texture can be divided into two categories. First, there are the multiple sets of texel arrays (a single array for the rectangular texture target; one set of mipmap arrays each for the one-, two-, and three-dimensional and one- and two-dimensional array texture targets; and six sets of mipmap arrays for the cube map texture targets) and their number. Each array has associated with it a width, height (two- and three-dimensional, rectangular, one-dimensional array, and cube map only), and depth (three-dimensional and two-dimensional array only), a border width, an integer describing the internal format of the image, integer values describing the resolutions of each of the red, green, blue, alpha, luminance, intensity, depth, and stencil components of the image, integer values describing the type (unsigned normalized, integer, floating-point, etc.) of each of the components, a boolean describing whether the image is compressed or not, and an integer size of a compressed image. Each initial texel array is null (zero width, height, and depth, zero border width, internal format 1, component sizes set to zero and component types set to NONE, the compressed flag set to FALSE, and a zero compressed size). Multisample textures contain an integer identifying the number of samples in each texel, and a boolean indicating whether identical sample locations and the same number of samples will be used for all texels in the image. The buffer texture target has associated an integer containing the name of the buffer object that provided the data store for the texture, initially zero, and an integer identifying the internal format of the texture, initially LUMINANCE8.

Next, there are the four sets of texture properties, corresponding to the one-, two-, three-dimensional, and cube map texture targets. Each set consists of the selected minification and magnification filters, the wrap modes for s, t (two- and three-dimensional and cube map only), and r (three-dimensional only), the TEXTURE_BORDER_COLOR, two floating-point numbers describing the minimum and maximum level of detail, two integers describing the base and maximum mipmap array, a boolean flag indicating whether the texture is resident, a boolean indicating whether automatic mipmap generation should be performed, the priority associated with each set of properties, and three integers describing the depth texture mode, compare mode, and compare function. The value of the resident flag is determined by the GL and may change as a result of other GL operations. The flag may only be queried, not set, by applications (see section 3.9.14). In the initial state, the value assigned to TEXTURE_MIN_FILTER is NEAREST_MIPMAP_LINEAR (except for rectangular textures, where the initial value is LINEAR), and the value for TEXTURE_MAG_FILTER is LINEAR. s, t, and r wrap modes are all set to REPEAT (except for rectangular textures, where the initial value is CLAMP_TO_EDGE). The values of TEXTURE_MIN_LOD and TEXTURE_MAX_LOD are -1000 and...
1000 respectively. The values of Texture_Base_Level and Texture_Max_Level are 0 and 1000 respectively. The value of Texture_Priority is 1.0. The value of Texture_Border_Color is (0,0,0,0). The value of Generate_Mipmap is false. The values of Depth_Texture_Mode, Texture_Compare_Mode, and Texture_Compare_Func are luminance, none, and lequal respectively. The initial value of Texture_Resident is determined by the GL.

In addition to image arrays for the non-proxy texture targets described above, partially instantiated image arrays are maintained for one-, two-, and three-dimensional, rectangular, and one- and two-dimensional array textures. Additionally, a single proxy image array is maintained for the cube map texture. Each proxy image array includes width, height, depth, border width, and internal format state values, as well as state for the red, green, blue, alpha, luminance, intensity, depth, and stencil component resolutions and types. Proxy arrays do not include image data nor texture parameters. When TexImage3D is executed with target specified as Proxy_Texture_3D, the three-dimensional proxy state values of the specified level-of-detail are recomputed and updated. If the image array would not be supported by TexImage3D called with target set to Texture_3D, no error is generated, but the proxy width, height, depth, border width, and component resolutions are set to zero, and the component types are set to none. If the image array would be supported by such a call to TexImage3D, the proxy state values are set exactly as though the actual image array were being specified. No pixel data are transferred or processed in either case.

Proxy arrays for one- and two-dimensional textures and one- and two-dimensional array textures are operated on in the same way when TexImage1D is executed with target specified as Proxy_Texture_1D, TexImage2D is executed with target specified as Proxy_Texture_2D, Proxy_Texture_1D_array, or Proxy_Texture_Rectangle, or TexImage3D is executed with target specified as Proxy_Texture_2D_array.

Proxy arrays for two-dimensional multisample and two-dimensional multisample array textures are operated on in the same way when TexImage2DMultisample is called with target specified as Proxy_Texture_2D_Multisample, or TexImage3DMultisample is called with target specified as Proxy_Texture_2D_Multisample_array.

The cube map proxy arrays are operated on in the same manner when TexImage2D is executed with the target field specified as Proxy_Texture_Cube_Map, with the addition that determining that a given cube map texture is supported with Proxy_Texture_Cube_Map indicates that all six of the cube map 2D images are supported. Likewise, if the specified Proxy_Texture_Cube_Map is not supported, none of the six cube map 2D images are supported.

There is no image or non-level-related state associated with proxy textures.
3.9. TEXTURING

Therefore they may not be used as textures, and calling `BindTexture`, `GetTexImage`, `GetTexParameteriv`, or `GetTexParameterfv` with a proxy texture target generates an `INVALID_ENUM` error.

### 3.9.14 Texture Objects

In addition to the default textures `TEXTURE_1D`, `TEXTURE_2D`, `TEXTURE_3D`, `TEXTURE_1D_ARRAY`, `TEXTURE_2D_ARRAY`, `TEXTURE_RECTANGLE`, `TEXTURE_BUFFER`, `TEXTURE_CUBE_MAP`, `TEXTURE_2D_MULTISAMPLE`, and `TEXTURE_2D_MULTISAMPLE_ARRAY`, named one-, two-, and three-dimensional, one- and two-dimensional array, rectangular, buffer, cube map, two-dimensional multisample, and two-dimensional multisample array texture objects can be created and operated upon. The name space for texture objects is the unsigned integers, with zero reserved by the GL.

A texture object is created by binding an unused name to one of these texture targets. The binding is effected by calling

```c
void BindTexture( enum target, uint texture );
```

with `target` set to the desired texture target and `texture` set to the unused name. The resulting texture object is a new state vector, comprising all the state values listed in section 3.9.13, set to the same initial values. The new texture object bound to `target` is, and remains a texture of the dimensionality and type specified by `target` until it is deleted.

`BindTexture` may also be used to bind an existing texture object to any of these targets. The error `INVALID_OPERATION` is generated if an attempt is made to bind a texture object of different dimensionality than the specified `target`. If the bind is successful no change is made to the state of the bound texture object, and any previous binding to `target` is broken.

While a texture object is bound, GL operations on the target to which it is bound affect the bound object, and queries of the target to which it is bound return state from the bound object. If texture mapping of the dimensionality of the target to which a texture object is bound is enabled, the state of the bound texture object directs the texturing operation.

In the initial state, `TEXTURE_1D`, `TEXTURE_2D`, `TEXTURE_3D`, `TEXTURE_1D_ARRAY`, `TEXTURE_2D_ARRAY`, `TEXTURE_RECTANGLE`, `TEXTURE_BUFFER`, `TEXTURE_2D_MULTISAMPLE`, and `TEXTURE_2D_MULTISAMPLE_ARRAY` have one-, two-, and three-dimensional, one- and two-dimensional array, rectangular, buffer, cube map, two-dimensional multisample, and two-dimensional multisample array texture state vectors respectively associated with them. In order that access
to these initial textures not be lost, they are treated as texture objects all of whose
names are 0. The initial one-, two-, three-dimensional, one- and two-dimensional
array, rectangular, buffer, and cube map texture is therefore operated upon, queried,
and applied as TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY,
TEXTURE_2D_ARRAY, TEXTURE_RECTANGLE, TEXTURE_BUFFER, TEXTURE_-CUBE_MAP, TEXTURE_2D_MULTISAMPLE, or TEXTURE_2D_MULTISAMPLE_-ARRAY respectively while 0 is bound to the corresponding targets.

Texture objects are deleted by calling

```c
void DeleteTextures( sizei n, uint *textures );
```

textures contains $n$ names of texture objects to be deleted. After a texture object
is deleted, it has no contents or dimensionality, and its name is again unused. If
a texture that is currently bound to any of the target bindings of BindTexture is
deleted, it is as though BindTexture had been executed with the same target and
texture zero. Additionally, special care must be taken when deleting a texture if any
of the images of the texture are attached to a framebuffer object. See section 4.4.2
for details.

Unused names in textures are silently ignored, as is the value zero.

The command

```c
void GenTextures( sizei n, uint *textures );
```

returns $n$ previously unused texture object names in textures. These names are
marked as used, for the purposes of GenTextures only, but they acquire texture
state and a dimensionality only when they are first bound, just as if they were
unused.

An implementation may choose to establish a working set of texture objects on
which binding operations are performed with higher performance. A texture object
that is currently part of the working set is said to be resident. The command

```c
boolean AreTexturesResident( sizei n, uint *textures,
    boolean *residences );
```

returns TRUE if all of the $n$ texture objects named in textures are resident, or if the
implementation does not distinguish a working set. If at least one of the texture
objects named in textures is not resident, then FALSE is returned, and the residence
of each texture object is returned in residences. Otherwise the contents of residences are not changed. If any of the names in textures are unused or are zero,
FALSE is returned, the error INVALID_VALUE is generated, and the contents of residences are indeterminate. The residence status of a single bound texture object
can also be queried by calling \texttt{GetTexParameteriv} or \texttt{GetTexParameterfv} with \textit{target} set to the target to which the texture object is bound, and \textit{pname} set to \texttt{TEXTURE_RESIDENT}.

\texttt{AreTexturesResident} indicates only whether a texture object is currently resident, not whether it could not be made resident. An implementation may choose to make a texture object resident only on first use, for example. The client may guide the GL implementation in determining which texture objects should be resident by specifying a priority for each texture object. The command

\begin{verbatim}
void PrioritizeTextures(sizei n, uint *textures,
    clampf *priorities);
\end{verbatim}

sets the priorities of the \(n\) texture objects named in \textit{textures} to the values in \textit{priorities}. Each priority value is clamped to the range \([0,1]\) before it is assigned. Zero indicates the lowest priority, with the least likelihood of being resident. One indicates the highest priority, with the greatest likelihood of being resident. The priority of a single bound texture object may also be changed by calling \texttt{TexParameter}, \texttt{TexParameterf}, \texttt{TexParameteriv}, or \texttt{TexParameterfv} with \textit{target} set to the target to which the texture object is bound, \textit{pname} set to \texttt{TEXTURE_PRIORITY}, and \textit{param} or \textit{params} specifying the new priority value (which is clamped to the range \([0,1]\) before being assigned). \texttt{PrioritizeTextures} silently ignores attempts to prioritize unused texture object names or zero (default textures).

The texture object name space, including the initial one-, two-, and three-dimensional, one- and two-dimensional array, rectangular, buffer, cube map, two-dimensional multisample, and two-dimensional multisample array texture objects, is shared among all texture units. A texture object may be bound to more than one texture unit simultaneously. After a texture object is bound, any GL operations on that target object affect any other texture units to which the same texture object is bound.

Texture binding is affected by the setting of the state \texttt{ACTIVE_TEXTURE}.

If a texture object is deleted, it as if all texture units which are bound to that texture object are rebound to texture object zero.

### 3.9.15 Texture Environments and Texture Functions

The command

\begin{verbatim}
void TexEnv{if}(enum target, enum pname, T param);
void TexEnv{if}v(enum target, enum pname, T params);
\end{verbatim}
sets parameters of the \textit{texture environment} that specifies how texture values are interpreted when texturing a fragment, or sets per-texture-unit filtering parameters.

\textit{target} must be one of \texttt{TEXTURE\_FILTER\_CONTROL}, \texttt{POINT\_SPRITE}, or \texttt{TEXTURE\_ENV}. \textit{pname} is a symbolic constant indicating the parameter to be set. In the first form of the command, \textit{param} is a value to which to set a single-valued parameter; in the second form, \textit{params} is a pointer to an array of parameters: either a single symbolic constant or a value or group of values to which the parameter should be set.

When \textit{target} is \texttt{TEXTURE\_FILTER\_CONTROL}, \textit{pname} must be \texttt{TEXTURE\_LOD\_BIAS}. In this case the parameter is a single signed floating point value, \texttt{bias}_\texttt{texunit}, that biases the level of detail parameter $\lambda$ as described in section 3.9.9.

When \textit{target} is \texttt{POINT\_SPRITE}, point sprite rasterization behavior is affected as described in section 3.4.

When \textit{target} is \texttt{TEXTURE\_ENV}, the possible environment parameters are \texttt{TEXTURE\_ENV\_MODE}, \texttt{TEXTURE\_ENV\_COLOR}, \texttt{COMBINE\_RGB}, \texttt{COMBINE\_ALPHA}, \texttt{RGB\_SCALE}, \texttt{ALPHA\_SCALE}, \texttt{SRCn\_RGB}, \texttt{SRCn\_ALPHA}, \texttt{OPERANDn\_RGB}, and \texttt{OPERANDn\_ALPHA}, where \textit{n} = 0, 1, or 2. \texttt{TEXTURE\_ENV\_MODE} may be set to one of \texttt{REPLACE}, \texttt{MODULATE}, \texttt{DECAL}, \texttt{BLEND}, \texttt{ADD}, or \texttt{COMBINE}. \texttt{TEXTURE\_ENV\_COLOR} is set to an RGBA color by providing four single-precision floating-point values. If integers are provided for \texttt{TEXTURE\_ENV\_COLOR}, then they are converted to floating-point as described in equation 2.2.

The value of \texttt{TEXTURE\_ENV\_MODE} specifies a \textit{texture function}. The result of this function depends on the fragment and the texel array value. The precise form of the function depends on the base internal formats of the texel arrays that were last specified.

\(C_f\) and \(A_f\) are the primary color components of the incoming fragment; \(C_s\) and \(A_s\) are the components of the texture source color, derived from the filtered texture values \(R_t, G_t, B_t\), \(A_t, L_t\), and \(I_t\) as shown in table 3.25; \(C_c\) and \(A_c\) are the components of the texture environment color; \(C_p\) and \(A_p\) are the components resulting from the previous texture environment (for texture environment 0, \(C_p\) and \(A_p\) are identical to \(C_f\) and \(A_f\), respectively); and \(C_v\) and \(A_v\) are the primary color components computed by the texture function.

If fragment color clamping is enabled, all of these color values, including the results, are clamped to the range [0, 1]. If fragment color clamping is disabled, the values are not clamped. The texture functions are specified in tables 3.26, 3.27, and 3.28.

\footnote{In the remainder of section 3.9.15, the notation \(C_x\) is used to denote each of the three components \(R_x, G_x\), and \(B_x\) of a color specified by \(x\). Operations on \(C_x\) are performed independently for each color component. The \(A\) component of colors is usually operated on in a different fashion, and is therefore denoted separately by \(A_x\).}

Table 3.27: Texture functions BLEND and ADD.

If the value of TEXTURE_ENV_MODE is COMBINE, the form of the texture function depends on the values of COMBINE_RGB and COMBINE_ALPHA, according to table 3.28. The RGB and ALPHA results of the texture function are then multiplied by the values of RGB_SCALE and ALPHA_SCALE, respectively. If fragment color clamping is enabled, the arguments and results used in table 3.28 are clamped to [0, 1]. Otherwise, the results are unmodified.

The arguments $Arg0$, $Arg1$, and $Arg2$ are determined by the values of $SRC_n_R$, $SRC_n_ALPHA$, $OPERAND_n_RGB$ and $OPERAND_n_ALPHA$, where $n = 0, 1, 2$, as shown in tables 3.29 and 3.30. $C_s^n$ and $A_s^n$ denote the texture source color and alpha from the texture image bound to texture unit $n$.

The state required for the current texture environment, for each texture unit, consists of a six-valued integer indicating the texture function, an eight-valued integer indicating the RGB combiner function and a six-valued integer indicating the ALPHA combiner function, six four-valued integers indicating the combiner RGB and ALPHA source arguments, three four-valued integers indicating the combiner RGB operands, three two-valued integers indicating the combiner ALPHA operands, and four floating-point environment color values. In the initial state, the texture and combiner functions are each MODULATE, the combiner RGB and ALPHA sources are each TEXTURE, PREVIOUS, and CONSTANT for sources 0, 1, and 2 respectively, the combiner RGB operands for sources 0 and 1 are each SRC_COLOR, the combiner RGB operand for source 2, as well as for the combiner ALPHA operands, are each...

**3.9. TEXTURING**

SRC_ALPHA, and the environment color is \((0, 0, 0, 0)\).

The state required for the texture filtering parameters, for each texture unit, consists of a single floating-point level of detail bias. The initial value of the bias is 0.0.

### 3.9.16 Texture Comparison Modes

Texture values can also be computed according to a specified comparison function. Texture parameter `TEXTURE_COMPARE_MODE` specifies the comparison operands, and parameter `TEXTURE_COMPARE_FUNC` specifies the comparison function. The format of the resulting texture sample is determined by the value of `DEPTH_TEXTURE_MODE`.

**Depth Texture Comparison Mode**

If the currently bound texture’s base internal format is `DEPTH_COMPONENT` or `DEPTH_STENCIL`, then `DEPTH_TEXTURE_MODE`, `TEXTURE_COMPARE_MODE` and `TEXTURE_COMPARE_FUNC` control the output of the texture unit as described below. Otherwise, the texture unit operates in the normal manner and texture comparison is bypassed.

Let \(D_t\) be the depth texture value and \(D_{ref}\) be the reference value, defined as follows:

- For fixed-function, non-cubemap texture lookups, \(D_{ref}\) is the interpolated \(r\) texture coordinate.
- For fixed-function, cubemap texture lookups, \(D_{ref}\) is the interpolated \(q\) texture coordinate.
- For texture lookups generated by an OpenGL Shading Language lookup function, \(D_{ref}\) is the reference value for depth comparisons provided by the lookup function.

If the texture’s internal format indicates a fixed-point depth texture, then \(D_t\) and \(D_{ref}\) are clamped to the range \([0, 1]\); otherwise no clamping is performed. Then the effective texture value is computed as follows:

If the value of `TEXTURE_COMPARE_MODE` is `NONE`, then

\[ r = D_t \]

If the value of `TEXTURE_COMPARE_MODE` is `COMPARE_REF_TO_TEXTURE`, then \(r\) depends on the texture comparison function as shown in table 3.31.
3.9. TEXTURING

<table>
<thead>
<tr>

<th>Computed result $r$</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEQUAL</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} \leq D_t \ 0.0, &amp; \text{if } D_{\text{ref}} &gt; D_t \end{cases}$</td>
</tr>
<tr>
<td>GEQUAL</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} \geq D_t \ 0.0, &amp; \text{if } D_{\text{ref}} &lt; D_t \end{cases}$</td>
</tr>
<tr>
<td>LESS</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} &lt; D_t \ 0.0, &amp; \text{if } D_{\text{ref}} \geq D_t \end{cases}$</td>
</tr>
<tr>
<td>GREATER</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} &gt; D_t \ 0.0, &amp; \text{if } D_{\text{ref}} \leq D_t \end{cases}$</td>
</tr>
<tr>
<td>EQUAL</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} = D_t \ 0.0, &amp; \text{if } D_{\text{ref}} \neq D_t \end{cases}$</td>
</tr>
<tr>
<td>NOTEQUAL</td>
<td>$r = \begin{cases} 1.0, &amp; \text{if } D_{\text{ref}} \neq D_t \ 0.0, &amp; \text{if } D_{\text{ref}} = D_t \end{cases}$</td>
</tr>
<tr>
<td>ALWAYS</td>
<td>$r = 1.0$</td>
</tr>
<tr>
<td>NEVER</td>
<td>$r = 0.0$</td>
</tr>
</tbody>
</table>

Table 3.31: Depth texture comparison functions.

The resulting $r$ is assigned to $R_t$, $L_t$, $I_t$, or $A_t$ if the value of `DEPTH_TEXTURE_MODE` is respectively `RED`, `LUMINANCE`, `INTENSITY`, or `ALPHA`.

If the value of `TEXTURE_MAG_FILTER` is not `NEAREST`, or the value of `TEXTURE_MIN_FILTER` is not `NEAREST` or `NEAREST_MIPMAP_NEAREST`, then $r$ may be computed by comparing more than one depth texture value to the texture reference value. The details of this are implementation-dependent, but $r$ should be a value in the range $[0, 1]$ which is proportional to the number of comparison passes or failures.

### 3.9.17 sRGB Texture Color Conversion

If the currently bound texture’s internal format is one of `SRGB`, `SRGB8`, `SRGB_ALPHA`, `SRGB8_ALPHA8`, `SLUMINANCE_ALPHA`, `SLUMINANCES8_ALPHA8`, `SLUMINANCE`, `SLUMINANCES8`, `COMPRESSED_SLUMINANCE`, `COMPRESSED_SLUMINANCE_ALPHA`, `COMPRESSED_SRGB`, or `COMPRESSED_SRGB_ALPHA`, the red, green, and blue components are converted from an sRGB color space to a linear color space as part of filtering described in sections 3.9.9 and 3.9.10. Any alpha component is left unchanged. Ideally, implementations should perform this
color conversion on each sample prior to filtering but implementations are allowed to perform this conversion after filtering (though this post-filtering approach is inferior to converting from sRGB prior to filtering).

The conversion from an sRGB encoded component, \( c_s \), to a linear component, \( c_l \), is as follows.

\[
  c_l = \begin{cases} 
    \frac{c_s}{12.92}, & c_s \leq 0.04045 \\
    \left( \frac{c_s + 0.055}{1.055} \right)^{2.4}, & c_s > 0.04045 
  \end{cases}
\]  

(3.28)

Assume \( c_s \) is the sRGB component in the range \([0, 1]\).

**3.9.18 Shared Exponent Texture Color Conversion**

If the currently bound texture’s internal format is `RGB9_E5`, the red, green, blue, and shared bits are converted to color components (prior to filtering) using shared exponent decoding. The component \( red_s \), \( green_s \), \( blue_s \), and \( exp_{\text{shared}} \) values (see section 3.9.1) are treated as unsigned integers and are converted to \( red \), \( green \), and \( blue \) as follows:

\[
  red = red_s 2^{exp_{\text{shared}} - B} \\
  green = green_s 2^{exp_{\text{shared}} - B} \\
  blue = blue_s 2^{exp_{\text{shared}} - B}
\]

**3.9.19 Texture Application**

Texturing is enabled or disabled using the generic `Enable` and `Disable` commands, respectively, with the symbolic constants `TEXTURE_1D`, `TEXTURE_2D`, `TEXTURE_3D`, or `TEXTURE_CUBE_MAP` to enable the one-, two-, three-dimensional, or cube map texture, respectively. If both two- and one-dimensional textures are enabled, the two-dimensional texture is used. If the three-dimensional and either of the two- or one-dimensional textures is enabled, the three-dimensional texture is used. If the cube map texture and any of the three-, two-, or one-dimensional textures is enabled, then cube map texturing is used.

If all texturing is disabled, a rasterized fragment is passed on unaltered to the next stage of the GL (although its texture coordinates may be discarded). Otherwise, a texture value is found according to the parameter values of the currently bound texture image of the appropriate dimensionality using the rules given in sections 3.9.8 through 3.9.10. This texture value is used along with the incoming fragment in computing the texture function indicated by the currently bound
texture environment. The result of this function replaces the incoming fragment’s primary R, G, B, and A values. These are the color values passed to subsequent operations. Other data associated with the incoming fragment remain unchanged, except that the texture coordinates may be discarded.

Note that the texture value may contain R, G, B, A, L, I, or D components, but it does not contain an S component. If the texture’s base internal format is DEPTH_STENCIL, for the purposes of texture application it is as if the base internal format were DEPTH_COMPONENT.

Each texture unit is enabled and bound to texture objects independently from the other texture units. Each texture unit follows the precedence rules for one-, two-, three-dimensional, and cube map textures. Thus texture units can be performing texture mapping of different dimensionalities simultaneously. Each unit has its own enable and binding states.

Each texture unit is paired with an environment function, as shown in figure 3.11. The second texture function is computed using the texture value from the second texture, the fragment resulting from the first texture function computation and the second texture unit’s environment function. If there is a third texture, the fragment resulting from the second texture function is combined with the third texture value using the third texture unit’s environment function and so on. The texture unit selected by ActiveTexture determines which texture unit’s environment is modified by TexEnv calls.

If the value of TEXTURE_ENV_MODE is COMBINE, the texture function associated with a given texture unit is computed using the values specified by SRCn_RGB, SRCn_ALPHA, OPERANDn_RGB and OPERANDn_ALPHA. If TEXTUREn is specified as SRCn_RGB or SRCn_ALPHA, the texture value from texture unit n will be used in computing the texture function for this texture unit.

Texturing is enabled and disabled individually for each texture unit. If texturing is disabled for one of the units, then the fragment resulting from the previous unit is passed unaltered to the following unit. Individual texture units beyond those specified by MAX_TEXTURE_UNITS are always treated as disabled.

If a texture unit is disabled or has an invalid or incomplete texture (as defined in section 3.9.12) bound to it, then blending is disabled for that texture unit. If the texture environment for a given enabled texture unit references a disabled texture unit, or an invalid or incomplete texture that is bound to another unit, then the results of texture blending are undefined.

The required state, per texture unit, is four bits indicating whether each of one-, two-, three-dimensional, or cube map texturing is enabled or disabled. In the initial state, all texturing is disabled for all texture units.
3.9. TEXTURING

TEXTURING

3.9. TEXTURING

Figure 3.11. Multitexture pipeline. Four texture units are shown; however, multitexturing may support a different number of units depending on the implementation. The input fragment color is successively combined with each texture according to the state of the corresponding texture environment, and the resulting fragment color passed as input to the next texture unit in the pipeline.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
3.10 Color Sum

At the beginning of color sum, a fragment has two RGBA colors: a primary color $c_{pri}$ (which texturing, if enabled, may have modified) and a secondary color $c_{sec}$.

If color sum is enabled, the R, G, and B components of these two colors are summed to produce a single post-texturing RGBA color $c$. The A component of $c$ is taken from the A component of $c_{pri}$; the A component of $c_{sec}$ is unused. If color sum is disabled, then $c_{pri}$ is assigned to $c$. If fragment color clamping is enabled, the components of $c$ are then clamped to the range $[0, 1]$.

Color sum is enabled or disabled using the generic **Enable** and **Disable** commands, respectively, with the symbolic constant **COLOR_SUM**. If lighting is enabled and if a vertex shader is not active, the color sum stage is always applied, ignoring the value of **COLOR_SUM**.

The state required is a single bit indicating whether color sum is enabled or disabled. In the initial state, color sum is disabled.

Color sum has no effect in color index mode, or if a fragment shader is active.

3.11 Fog

If enabled, fog blends a fog color with a rasterized fragment’s post-texturing color using a blending factor $f$. Fog is enabled and disabled with the **Enable** and **Disable** commands using the symbolic constant **FOG**.

This factor $f$ is computed according to one of three equations:

$$ f = \exp(-d \cdot c), $$

$$ f = \exp(- (d \cdot c)^2), \text{ or } $$  

$$ f = \frac{e - c}{e - s} $$  

If a vertex or geometry shader is active, or if the fog source, as defined below, is **FOG_COORD**, then $c$ is the interpolated value of the fog coordinate for this fragment. Otherwise, if the fog source is **FRAGMENT_DEPTH**, then $c$ is the eye-coordinate distance from the eye, $(0, 0, 0, 1)$ in eye coordinates, to the fragment center. The equation and the fog source, along with either $d$ or $e$ and $s$, is specified with

```c
void Fog{if}(enum pname, T param);
void Fog{if}v(enumerator name, T params);
```
If `pname` is `FOG_MODE`, then `param` must be, or `params` must point to an integer that is one of the symbolic constants `EXP`, `EXP2`, or `LINEAR`, in which case equation 3.29, 3.30, or 3.31, respectively, is selected for the fog calculation (if, when 3.31 is selected, $e = s$, results are undefined). If `pname` is `FOG_COORD_SRC`, then `param` must be, or `params` must point to an integer that is one of the symbolic constants `FRAGMENT_DEPTH` or `FOG_COORD`. If `pname` is `FOG_DENSITY`, `FOG_START`, or `FOG_END`, then `param` is or `params` points to a value that is $d$, $s$, or $e$, respectively. If $d$ is specified less than zero, the error `INVALID_VALUE` results.

An implementation may choose to approximate the eye-coordinate distance from the eye to each fragment center by $|z_e|$. Further, $f$ need not be computed at each fragment, but may be computed at each vertex and interpolated as other data are.

No matter which equation and approximation is used to compute $f$, the result is clamped to $[0, 1]$ to obtain the final $f$.

$f$ is used differently depending on whether the GL is in RGBA or color index mode. In RGBA mode, if $C_r$ represents a rasterized fragment’s R, G, or B value, then the corresponding value produced by fog is

$$C = fC_r + (1 - f)C_f.$$  

(The rasterized fragment’s A value is not changed by fog blending.) The R, G, B, and A values of $C_f$ are specified by calling `Fog` with `pname` equal to `FOG_COLOR`; in this case `params` points to four values comprising $C_f$. If these are not floating-point values, then they are converted to floating-point as described in equation 2.2. If fragment color clamping is enabled, the components of $C_r$ and $C_f$ and the result $C$ are clamped to the range $[0, 1]$ before the fog blend is performed.

In color index mode, the formula for fog blending is

$$I = i_r + (1 - f)i_f$$

where $i_r$ is the rasterized fragment’s color index and $i_f$ is a single-precision floating-point value. $(1 - f)i_f$ is rounded to the nearest fixed-point value with the same number of bits to the right of the binary point as $i_r$, and the integer portion of $I$ is masked (bitwise ANDed) with $2^n - 1$, where $n$ is the number of bits in a color in the color index buffer (buffers are discussed in chapter 4). The value of $i_f$ is set by calling `Fog` with `pname` set to `FOG_INDEX` and `param` being or `params` pointing to a single value for the fog index. The integer part of $i_f$ is masked with $2^n - 1$.

The state required for fog consists of a three valued integer to select the fog equation, three floating-point values $d$, $e$, and $s$, an RGBA fog color and a fog color index, a two-valued integer to select the fog coordinate source, and a single
bit to indicate whether or not fog is enabled. In the initial state, fog is disabled, FOG_COORD_SRC is FRAGMENT_DEPTH, FOG_MODE is EXP, \( d = 1.0 \), \( e = 1.0 \), and \( s = 0.0 \); \( C_f = (0, 0, 0, 0) \) and \( i_f = 0 \).

Fog has no effect if a fragment shader is active.

### 3.12 Fragment Shaders

The sequence of operations that are applied to fragments that result from rasterizing a point, line segment, polygon, pixel rectangle or bitmap as described in sections 3.9 through 3.11 is a fixed-functionality method for processing such fragments. Applications can more generally describe the operations that occur on such fragments by using a fragment shader.

A fragment shader is an array of strings containing source code for the operations that are meant to occur on each fragment that results from rasterization. The language used for fragment shaders is described in the OpenGL Shading Language Specification.

A fragment shader only applies when the GL is in RGBA mode. Its operation in color index mode is undefined.

Fragment shaders are created as described in section 2.14.1 using a type parameter of FRAGMENT_SHADER. They are attached to and used in program objects as described in section 2.14.2.

When the program object currently in use includes a fragment shader, its fragment shader is considered active, and is used to process fragments. If the program object has no fragment shader, or no program object is currently in use, the fixed-function fragment processing operations described in previous sections are used instead.

Results of rasterization are undefined if any of the selected draw buffers of the draw framebuffer have an integer format and no fragment shader is active.

### 3.12.1 Shader Variables

Fragment shaders can access uniforms belonging to the current shader object. The amount of storage available for fragment shader uniform variables in the default uniform block is specified by the value of the implementation-dependent constant MAX_FRAGMENT_UNIFORM_COMPONENTS. The total amount of combined storage available for fragment shader uniform variables in all uniform blocks (including the default uniform block) is specified by the value of the implementation-dependent constant MAX_COMBINED_FRAGMENT_UNIFORM_COMPONENTS. These values represent the numbers of individual floating-point, integer, or boolean values that can
be held in uniform variable storage for a fragment shader. A uniform matrix will consume no more than $4 \times \min(r, c)$ such values, where $r$ and $c$ are the number of rows and columns in the matrix. A link error will be generated if an attempt is made to utilize more than the space available for fragment shader uniform variables.

Fragment shaders can read varying variables that correspond to the attributes of the fragments produced by rasterization. The OpenGL Shading Language Specification defines a set of built-in varying variables that can be accessed by a fragment shader. These built-in varying variables include data associated with a fragment that are used for fixed-function fragment processing, such as the fragment’s color, secondary color, texture coordinates, fog coordinate, eye $z$ coordinate, and position.

Additionally, when a vertex shader is active, it may define one or more varying variables (see section 2.14.6 and the OpenGL Shading Language Specification). These values are, if not flat shaded, interpolated across the primitive being rendered. The results of these interpolations are available when varying variables of the same name are defined in the fragment shader.

User-defined varying variables are not saved in the current raster position. When processing fragments generated by the rasterization of a pixel rectangle or bitmap, values of user-defined varying variables are undefined. Built-in varying variables have well-defined values.

A fragment shader can also write to varying out variables. Values written to these variables are used in the subsequent per-fragment operations. Varying out variables can be used to write floating-point, integer or unsigned integer values destined for buffers attached to a framebuffer object, or destined for color buffers attached to the default framebuffer. The Shader Outputs subsection of section 3.12.2 describes how to direct these values to buffers.

### 3.12.2 Shader Execution

If a fragment shader is active, the executable version of the fragment shader is used to process incoming fragment values that are the result of rasterization, rather than the fixed-function fragment processing described in sections 3.9 through 3.11. In particular,

- The texture environments and texture functions described in section 3.9.15 are not applied.
- Texture application as described in section 3.9.19 is not applied.
- Color sum as described in section 3.10 is not applied.
3.12. FRAGMENT SHADERS

- Fog as described in section 3.11 is not applied.

Texture Access

The Shader Only Texturing subsection of section 2.14.7 describes texture lookup functionality accessible to a vertex shader. The texel fetch and texture size query functionality described there also applies to fragment shaders.

When a texture lookup is performed in a fragment shader, the GL computes the filtered texture value $\tau$ in the manner described in sections 3.9.9 and 3.9.10, and converts it to a texture source color $C_s$ according to table 3.25 (section 3.9.15). The GL returns a four-component vector $(R_s, G_s, B_s, A_s)$ to the fragment shader.

For the purposes of level-of-detail calculations, the derivatives $\frac{du}{dx}, \frac{du}{dy}, \frac{dv}{dx}, \frac{dv}{dy}, \frac{dw}{dx}$ and $\frac{dw}{dy}$ may be approximated by a differencing algorithm as detailed in section 8.8 of the OpenGL Shading Language Specification.

Texture lookups involving textures with depth component data can either return the depth data directly or return the results of a comparison with the $D_{ref}$ value (see section 3.9.16) used to perform the lookup. The comparison operation is requested in the shader by using any of the shadow sampler types (sampler1DShadow, sampler2DShadow, or sampler2DRectShadow), and in the texture using the TEXTURE_COMPARE_MODE parameter. These requests must be consistent; the results of a texture lookup are undefined if:

- The sampler used in a texture lookup function is not one of the shadow sampler types, the texture object’s internal format is DEPTH_COMPONENT or DEPTH_STENCIL, and the TEXTURE_COMPARE_MODE is not NONE.

- The sampler used in a texture lookup function is one of the shadow sampler types, the texture object’s internal format is DEPTH_COMPONENT or DEPTH_STENCIL, and the TEXTURE_COMPARE_MODE is NONE.

- The sampler used in a texture lookup function is one of the shadow sampler types, and the texture object’s internal format is not DEPTH_COMPONENT or DEPTH_STENCIL.

The stencil index texture internal component is ignored if the base internal format is DEPTH_STENCIL.

Using a sampler in a fragment shader will return $(R, G, B, A) = (0, 0, 0, 1)$ if the sampler’s associated texture is not complete, as defined in section 3.9.12.

The number of separate texture units that can be accessed from within a fragment shader during the rendering of a single primitive is specified by the implementation-dependent constant MAX_TEXTURE_IMAGE_UNITS.
Shader Inputs

The OpenGL Shading Language Specification describes the values that are available as inputs to the fragment shader.

The built-in variable `gl_FragCoord` holds the fragment coordinate \((x_f \ y_f \ z_f \ w_f)\) for the fragment. Computing the fragment coordinate depends on the fragment processing pixel-center and origin conventions (discussed below) as follows:

\[
x_f = \begin{cases} 
  x_w - \frac{1}{2}, & \text{pixel-center convention is integer} \\
  x_w, & \text{otherwise}
\end{cases}
\]

\[
y_f' = \begin{cases} 
  H - y_w, & \text{origin convention is upper-left} \\
  y_w, & \text{otherwise}
\end{cases}
\]

\[
y_f = \begin{cases} 
  y_f' - \frac{1}{2}, & \text{pixel-center convention is integer} \\
  y_f', & \text{otherwise}
\end{cases}
\]

\[
z_f = z_w
\]

\[
w_f = \frac{1}{w_c}
\]

where \((x_w \ y_w \ z_w)\) is the fragment’s window-space position, \(w_c\) is the \(w\) component of the fragment’s clip-space position, and \(H\) is the window’s height in pixels. Note that \(z_w\) already has a polygon offset added in, if enabled (see section 3.6.5). \(z_f\) must be precisely 0 or 1 in the case where \(z_w\) is either 0 or 1, respectively. The \(\frac{1}{w_c}\) value is computed from the \(w_c\) coordinate (see section 2.16), which is the result of the product of the projection matrix and the vertex’s eye coordinates.

Unless otherwise specified by layout qualifiers in the fragment shader (see section 4.3.8.1 of the OpenGL Shading Language Specification), the fragment processing pixel-center convention is half-integer and the fragment processing origin convention is lower-left.

The built-in variables `gl_Color` and `gl_SecondaryColor` hold the R, G, B, and A components, respectively, of the fragment color and secondary color. If the primary color or the secondary color components are represented by the GL as fixed-point values, they undergo an implied conversion to floating-point. This conversion must leave the values 0 and 1 invariant. Floating-point color components (resulting from a disabled vertex color clamp) are unmodified.

The built-in variable `gl_FrontFacing` is set to `TRUE` if the fragment is generated from a front-facing primitive, and `FALSE` otherwise. For fragments generated from quadrilateral, polygon, or triangle primitives (including ones resulting from...
primitives rendered as points or lines), the determination is made by examining the sign of the area computed by equation 3.8 of section 3.6.1 (including the possible reversal of this sign controlled by FrontFace). If the sign is positive, fragments generated by the primitive are front-facing; otherwise, they are back-facing. All other fragments are considered front-facing.

If a geometry shader is active, the built-in variable gl_PrimitiveID contains the ID value emitted by the geometry shader for the provoking vertex. If no geometry shader is active, gl_PrimitiveID contains the number of primitives processed by the rasterizer since the last time Begin was called (directly or indirectly via vertex array functions). The first primitive generated after a Begin is numbered zero, and the primitive ID counter is incremented after every individual point, line, or polygon primitive is processed. For polygons drawn in point or line mode, the primitive ID counter is incremented only once, even though multiple points or lines may be drawn. For QUADS and QUAD_STRIP primitives that are decomposed into triangles, the primitive ID is incremented after each complete quad is processed.

Restarting a primitive using the primitive restart index (see section 2.8) has no effect on the primitive ID counter.

The value of gl_PrimitiveID is undefined for fragments generated by POLYGON primitives or from DrawPixels or Bitmap commands. Additionally, gl_PrimitiveID is only defined under the same conditions that gl_VertexID is defined, as described under “Shader Inputs” in section 2.14.4.

Similarly to the limit on geometry shader output components (see section 2.15.4), there is a limit on the number of components of built-in and user-defined input varying variables that can be read by the fragment shader, given by the value of the implementation-dependent constant MAX_FRAGMENT_INPUT_COMPONENTS.

When a program is linked, all components of any varying and special variable read by a fragment shader will count against this limit. A program whose fragment shader reads more than the value of MAX_FRAGMENT_INPUT_COMPONENTS components worth of varying variables may fail to link, unless device-dependent optimizations are able to make the program fit within available hardware resources.

**Shader Outputs**

The OpenGL Shading Language Specification describes the values that may be output by a fragment shader. These outputs are split into two categories, user-defined varying out variables and the built-in variables gl_FragColor, gl_FragData[n], and gl_FragDepth. If fragment color clamping is enabled and the color buffer has an unsigned normalized fixed-point, signed normalized fixed-
point, or floating-point format, the final fragment color, fragment data, or varying out variable values written by a fragment shader are clamped to the range [0, 1]. Only user-defined varying out variables declared as a floating-point type are clamped and may be converted. If fragment color clamping is disabled, or the color buffer has an integer format, the final fragment color, fragment data, or varying out variable values are not modified. For fixed-point depth buffers, the final fragment depth written by a fragment shader is first clamped to [0, 1] and then converted to fixed-point as if it were a window z value (see section 2.16.1). For floating-point depth buffers, conversion is not performed but clamping is. Note that the depth range computation is not applied here, only the conversion to fixed-point.

Color values written by a fragment shader may be floating-point, signed integer, or unsigned integer. If the color buffer has an signed or unsigned normalized fixed-point format, color values are assumed to be floating-point and are converted to fixed-point as described in equations 2.6 or 2.4, respectively; otherwise no type conversion is applied. If the values written by the fragment shader do not match the format(s) of the corresponding color buffer(s), the result is undefined.

Writing to `gl_FragColor` specifies the fragment color (color number zero) that will be used by subsequent stages of the pipeline. Writing to `gl_FragData[n]` specifies the value of fragment color number n. Any colors, or color components, associated with a fragment that are not written by the fragment shader are undefined. A fragment shader may not statically assign values to more than one of `gl_FragColor`, `gl_FragData`, and any user-defined varying out variable. In this case, a compile or link error will result. A shader statically assigns a value to a variable if, after pre-processing, it contains a statement that would write to the variable, whether or not run-time flow of control will cause that statement to be executed.

Writing to `gl_FragDepth` specifies the depth value for the fragment being processed. If the active fragment shader does not statically assign a value to `gl_FragDepth`, then the depth value generated during rasterization is used by subsequent stages of the pipeline. Otherwise, the value assigned to `gl_FragDepth` is used, and is undefined for any fragments where statements assigning a value to `gl_FragDepth` are not executed. Thus, if a shader statically assigns a value to `gl_FragDepth`, then it is responsible for always writing it.

The binding of a user-defined varying out variable to a fragment color number can be specified explicitly. The command

```c
void BindFragDataLocation( uint program,
    uint colorNumber, const char *name );
```

specifies that the varying out variable `name` in `program` should be bound to fragment color `colorNumber` when the program is next linked. If `name` was bound
3.13. ANTIALIASING APPLICATION

previously, its assigned binding is replaced with \textit{colorNumber}. \textit{name} must be a null-terminated string. The error \texttt{INVALID\_VALUE} is generated if \textit{colorNumber} is equal or greater than \texttt{MAX\_DRAW\_BUFFERS}. \texttt{BindFragDataLocation} has no effect until the program is linked. In particular, it doesn’t modify the bindings of varying out variables in a program that has already been linked. The error \texttt{INVALID\_OPERATION} is generated if \textit{name} starts with the reserved \texttt{gl} prefix.

When a program is linked, any varying out variables without a binding specified through \texttt{BindFragDataLocation} will automatically be bound to fragment colors by the GL. Such bindings can be queried using the command \texttt{GetFragDataLocation}. \texttt{LinkProgram} will fail if the number of active outputs is greater than the value of \texttt{MAX\_DRAW\_BUFFERS}. \texttt{LinkProgram} will also fail if more than one varying out variable is bound to the same number. This type of aliasing is not allowed.

\texttt{BindFragDataLocation} may be issued before any shader objects are attached to a program object. Hence it is allowed to bind any name (except a name starting with \texttt{gl}) to a color number, including a name that is never used as a varying out variable in any fragment shader object. Assigned bindings for variables that do not exist are ignored.

After a program object has been linked successfully, the bindings of varying out variable names to color numbers can be queried. The command

\begin{verbatim}
int GetFragDataLocation( uint program, const char *name );
\end{verbatim}

returns the number of the fragment color to which the varying out variable \textit{name} was bound when the program object \textit{program} was last linked. \textit{name} must be a null-terminated string. If \textit{program} has not been successfully linked, the error \texttt{INVALID\_OPERATION} is generated. If \textit{name} is not a varying out variable, or if an error occurs, -1 will be returned.

3.13 Antialiasing Application

If antialiasing is enabled for the primitive from which a rasterized fragment was produced, then the computed coverage value is applied to the fragment. In RGBA mode, the value is multiplied by the fragment’s alpha (A) value to yield a final alpha value. In color index mode, the value is used to set the low order bits of the color index value as described in section 3.3. The coverage value is applied separately to each fragment color, and only applied if the corresponding color buffer in the framebuffer has a fixed- or floating-point format.
3.14 Multisample Point Fade

Finally, if multisampling is enabled and the rasterized fragment results from a point primitive, then the computed fade factor from equation 3.2 is applied to the fragment. In RGBA mode, the fade factor is multiplied by the fragment’s alpha value to yield a final alpha value. In color index mode, the fade factor has no effect. The fade factor is applied separately to each fragment color, and only applied if the corresponding color buffer in the framebuffer has a fixed- or floating-point format.
Chapter 4

Per-Fragment Operations and the Framebuffer

The framebuffer, whether it is the default framebuffer or a framebuffer object (see section 2.1), consists of a set of pixels arranged as a two-dimensional array. For purposes of this discussion, each pixel in the framebuffer is simply a set of some number of bits. The number of bits per pixel may vary depending on the GL implementation, the type of framebuffer selected, and parameters specified when the framebuffer was created. Creation and management of the default framebuffer is outside the scope of this specification, while creation and management of framebuffer objects is described in detail in section 4.4.

Corresponding bits from each pixel in the framebuffer are grouped together into a bitplane; each bitplane contains a single bit from each pixel. These bitplanes are grouped into several logical buffers. These are the color, accumulation, depth, and stencil buffers. The color buffer actually consists of a number of buffers, and these color buffers serve related but slightly different purposes depending on whether the GL is bound to the default framebuffer or a framebuffer object.

For the default framebuffer, the color buffers are the front left buffer, the front right buffer, the back left buffer, the back right buffer, and some number of auxiliary buffers. Typically the contents of the front buffers are displayed on a color monitor while the contents of the back buffers are invisible. (Monoscopic contexts display only the front left buffer; stereoscopic contexts display both the front left and the front right buffers.) The contents of the auxiliary buffers are never visible. All color buffers must have the same number of bitplanes, although an implementation or context may choose not to provide right buffers, back buffers, or auxiliary buffers at all. Further, an implementation or context may choose not to provide accumulation, depth or stencil buffers. If no default framebuffer is associated with
the GL context, the framebuffer is incomplete except when a framebuffer object is bound (see sections 4.4.1 and 4.4.4).

Framebuffer objects are not visible, and do not have any of the color buffers present in the default framebuffer. Instead, the buffers of a framebuffer object are specified by attaching individual textures or renderbuffers (see section 4.4) to a set of attachment points. A framebuffer object has an array of color buffer attachment points, numbered zero through \( n \), a depth buffer attachment point, and a stencil buffer attachment point. In order to be used for rendering, a framebuffer object must be complete, as described in section 4.4.4. Not all attachments of a framebuffer object need to be populated.

Each pixel in a color buffer consists of either a single unsigned integer color index or up to four color components. The four color components are named R, G, B, and A, in that order; color buffers are not required to have all four color components. R, G, B, and A components may be represented as signed or unsigned normalized fixed-point, floating-point, or signed or unsigned integer values; all components must have the same representation. Each pixel in a depth buffer consists of a single unsigned integer value in the format described in section 2.16.1 or a floating-point value. Each pixel in a stencil buffer consists of a single unsigned integer value. Each pixel in an accumulation buffer consists of up to four color components. If an accumulation buffer is present, it must have at least as many bitplanes per component as in the color buffers.

The number of bitplanes in the accumulation, color, depth, and stencil buffers is dependent on the currently bound framebuffer. For the default framebuffer, the number of bitplanes is fixed. For framebuffer objects, the number of bitplanes in a given logical buffer may change if the image attached to the corresponding attachment point changes.

The GL has two active framebuffers; the draw framebuffer is the destination for rendering operations, and the read framebuffer is the source for readback operations. The same framebuffer may be used for both drawing and reading. Section 4.4.1 describes the mechanism for controlling framebuffer usage.

The default framebuffer is initially used as the draw and read framebuffer, and the initial state of all provided bitplanes is undefined. The format and encoding of buffers in the draw and read framebuffers can be queried as described in section 6.1.3.

---

1 The window system binding API may allow associating a GL context with two separate “default framebuffers” provided by the window system as the draw and read framebuffers, but if so, both default framebuffers are referred to by the name zero at their respective binding points.
4.1 Per-Fragment Operations

A fragment produced by rasterization with window coordinates of \((x_w, y_w)\) modifies the pixel in the framebuffer at that location based on a number of parameters and conditions. We describe these modifications and tests, diagrammed in figure 4.1, in the order in which they are performed. Figure 4.1 diagrams these modifications and tests.

4.1.1 Pixel Ownership Test

The first test is to determine if the pixel at location \((x_w, y_w)\) in the framebuffer is currently owned by the GL (more precisely, by this GL context). If it is not, the window system decides the fate the incoming fragment. Possible results are that the fragment is discarded or that some subset of the subsequent per-fragment operations are applied to the fragment. This test allows the window system to control the GL’s behavior, for instance, when a GL window is obscured.

If the draw framebuffer is a framebuffer object (see section 4.2.1), the pixel ownership test always passes, since the pixels of framebuffer objects are owned by the GL, not the window system. If the draw framebuffer is the default framebuffer,
4.1. **PER-FRAGMENT OPERATIONS**

the window system controls pixel ownership.

### 4.1.2 Scissor Test

The scissor test determines if \((x_w, y_w)\) lies within the scissor rectangle defined by four values. These values are set with

```c
void Scissor( int left, int bottom, sizei width, sizei height );
```

If \(left \leq x_w < left + width\) and \(bottom \leq y_w < bottom + height\), then the scissor test passes. Otherwise, the test fails and the fragment is discarded. The test is enabled or disabled using `Enable` or `Disable` using the constant `SCISSOR_TEST`. When disabled, it is as if the scissor test always passes. If either \(width\) or \(height\) is less than zero, then the error `INVALID_VALUE` is generated. The state required consists of four integer values and a bit indicating whether the test is enabled or disabled. In the initial state, \(left = bottom = 0\), \(width\) and \(height\) are set to the width and height, respectively, of the window into which the GL is to do its rendering. If the default framebuffer is bound but no default framebuffer is associated with the GL context (see chapter 4), then \(width\) and \(height\) are initially set to zero. Initially, the scissor test is disabled.

### 4.1.3 Multisample Fragment Operations

This step modifies fragment alpha and coverage values based on the values of `SAMPLE_ALPHA_TO_COVERAGE`, `SAMPLE_ALPHA_TO_ONE`, `SAMPLE_COVERAGE`, `SAMPLE_COVERAGE_VALUE`, `SAMPLE_COVERAGE_INVERT`, `SAMPLE_MASK`, and `SAMPLE_MASK_VALUE`. No changes to the fragment alpha or coverage values are made at this step if `MULTISAMPLE` is disabled, or if the value of `SAMPLE_BUFFERS` is not one.

`SAMPLE_ALPHA_TO_COVERAGE`, `SAMPLE_ALPHA_TO_ONE`, and `SAMPLE_COVERAGE` are enabled and disabled by calling `Enable` and `Disable` with `cap` specified as one of the three token values. All three values are queried by calling `IsEnabled` with `cap` set to the desired token value. If `SAMPLE_ALPHA_TO_COVERAGE` is enabled and the color buffer has a fixed-point or floating-point format, a temporary coverage value is generated where each bit is determined by the alpha value at the corresponding sample location. The temporary coverage value is then ANDed with the fragment coverage value. Otherwise the fragment coverage value is unchanged at this point. If multiple colors are written by a fragment shader, the alpha value of fragment color zero is used to determine the temporary coverage value.
4.1. PER-FRAGMENT OPERATIONS

No specific algorithm is required for converting the sample alpha values to a temporary coverage value. It is intended that the number of 1’s in the temporary coverage be proportional to the set of alpha values for the fragment, with all 1’s corresponding to the maximum of all alpha values, and all 0’s corresponding to all alpha values being 0. The alpha values used to generate a coverage value are clamped to the range [0, 1]. It is also intended that the algorithm be pseudo-random in nature, to avoid image artifacts due to regular coverage sample locations. The algorithm can and probably should be different at different pixel locations. If it does differ, it should be defined relative to window, not screen, coordinates, so that rendering results are invariant with respect to window position.

Next, if \texttt{SAMPLE\_ALPHA\_TO\_ONE} is enabled, each alpha value is replaced by the maximum representable alpha value. Otherwise, the alpha values are not changed.

Next, if \texttt{SAMPLE\_COVERAGE} is enabled, the fragment coverage is ANDed with another temporary coverage. This temporary coverage is generated in the same manner as the one described above, but as a function of the value of \texttt{SAMPLE\_COVERAGE\_VALUE}. The function need not be identical, but it must have the same properties of proportionality and invariance. If \texttt{SAMPLE\_COVERAGE\_INVERT} is \texttt{TRUE}, the temporary coverage is inverted (all bit values are inverted) before it is ANDed with the fragment coverage.

The values of \texttt{SAMPLE\_COVERAGE\_VALUE} and \texttt{SAMPLE\_COVERAGE\_INVERT} are specified by calling

```c
void SampleCoverage( clampf value, boolean invert );
```

with \texttt{value} set to the desired coverage value, and \texttt{invert} set to \texttt{TRUE} or \texttt{FALSE}. \texttt{value} is clamped to [0,1] before being stored as \texttt{SAMPLE\_COVERAGE\_VALUE}. \texttt{SAMPLE\_COVERAGE\_VALUE} is queried by calling \texttt{GetFloatv} with \texttt{pname} set to \texttt{SAMPLE\_COVERAGE\_VALUE}. \texttt{SAMPLE\_COVERAGE\_INVERT} is queried by calling \texttt{GetBooleanv} with \texttt{pname} set to \texttt{SAMPLE\_COVERAGE\_INVERT}.

Finally, if \texttt{SAMPLE\_MASK} is enabled, the fragment coverage is ANDed with the coverage value \texttt{SAMPLE\_MASK\_VALUE}. The value of \texttt{SAMPLE\_MASK\_VALUE} is specified using

```c
void SampleMaski( uint maskNumber, bitfield mask );
```

with \texttt{mask} set to the desired mask for mask word \texttt{maskNumber}. \texttt{SAMPLE\_MASK\_VALUE} is queried by calling \texttt{GetIntegeriv} with \texttt{pname} set to \texttt{SAMPLE\_MASK\_VALUE} and the index set to \texttt{maskNumber}. Bit \texttt{B} of mask word \texttt{M} corresponds to sample \(32 \times M + B\) as described in section 3.3.1. The error \texttt{INVALID\_VALUE} is generated if the mask word indexed is greater than or equal to the value of \texttt{MAX\_SAMPLE\_MASK\_WORDS}.
4.1.4 Alpha Test

This step applies only in RGBA mode, and only if the color buffer has a fixed-point or floating-point format. In color index mode, or if the color buffer has an integer format, proceed to the next operation.

The alpha test discards a fragment conditional on the outcome of a comparison between the incoming fragment’s alpha value and a constant value. If multiple colors are written by a fragment shader, the alpha value of fragment color zero is used to determine the result of the alpha test. The comparison is enabled or disabled with the generic Enable and Disable commands using the symbolic constant ALPHA_TEST. When disabled, it is as if the comparison always passes. The test is controlled with

```c
void AlphaFunc(enum func, clampf ref);
```

`func` is a symbolic constant indicating the alpha test function; `ref` is a reference value. When performing the alpha test, the GL will convert the reference value to the same representation as the the fragment’s alpha value (floating-point or fixed-point). For fixed-point, the reference value is converted according to equation 2.4 using the bit-width rule for an A component described in section 2.1.5, and the fragment’s alpha value is rounded to the nearest integer.

The possible constants specifying the test function are NEVER, ALWAYS, LESS, LEQUAL, EQUAL, GEQUAL, GREATER, or NOTEQUAL, meaning pass the fragment never, always, if the fragment’s alpha value is less than, less than or equal to, equal to, greater than or equal to, greater than, or not equal to the reference value, respectively.

The required state consists of the floating-point reference value, an eight-valued integer indicating the comparison function, and a bit indicating if the comparison is enabled or disabled. The initial state is for the reference value to be 0 and the function to be ALWAYS. Initially, the alpha test is disabled.

4.1.5 Stencil Test

The stencil test conditionally discards a fragment based on the outcome of a comparison between the value in the stencil buffer at location \((x_w, y_w)\) and a reference value. The test is enabled or disabled with the Enable and Disable commands, using the symbolic constant STENCIL_TEST. When disabled, the stencil test and associated modifications are not made, and the fragment is always passed.

The stencil test is controlled with

```c
void StencilFunc(enum func, int ref, uint mask);
```
void StencilFuncSeparate(enum face, enum func, int ref, uint mask);
void StencilOp(enum sfail, enum dpfail, enum dppass);
void StencilOpSeparate(enum face, enum sfail, enum dpfail, enum dppass);

There are two sets of stencil-related state, the front stencil state set and the back stencil state set. Stencil tests and writes use the front set of stencil state when processing fragments rasterized from non-polygon primitives (points, lines, bitmaps, and image rectangles) and front-facing polygon primitives while the back set of stencil state is used when processing fragments rasterized from back-facing polygon primitives. For the purposes of stencil testing, a primitive is still considered a polygon even if the polygon is to be rasterized as points or lines due to the current polygon mode. Whether a polygon is front- or back-facing is determined in the same manner used for two-sided lighting and face culling (see sections 2.13.1 and 3.6.1).

StencilFuncSeparate and StencilOpSeparate take a face argument which can be FRONT, BACK, or FRONT_AND_BACK and indicates which set of state is affected. StencilFunc and StencilOp set front and back stencil state to identical values.

StencilFunc and StencilFuncSeparate take three arguments that control whether the stencil test passes or fails. ref is an integer reference value that is used in the unsigned stencil comparison. Stencil comparison operations and queries of ref clamp its value to the range \([0, 2^s - 1]\), where \(s\) is the number of bits in the stencil buffer attached to the draw framebuffer. The \(s\) least significant bits of mask are bitwise ANDed with both the reference and the stored stencil value, and the resulting masked values are those that participate in the comparison controlled by func. func is a symbolic constant that determines the stencil comparison function; the eight symbolic constants are NEVER, ALWAYS, LESS, LEQUAL, EQUAL, GEQUAL, GREATER, or NOTEQUAL. Accordingly, the stencil test passes never, always, and if the masked reference value is less than, less than or equal to, equal to, greater than or equal to, greater than, or not equal to the masked stored value in the stencil buffer.

StencilOp and StencilOpSeparate take three arguments that indicate what happens to the stored stencil value if this or certain subsequent tests fail or pass. sfail indicates what action is taken if the stencil test fails. The symbolic constants are KEEP, ZERO, REPLACE, INCR, DECR, INVERT, INCR_WRAP, and DECR_WRAP. These correspond to keeping the current value, setting to zero, replacing with the reference value, incrementing with saturation, decrementing with saturation, bitwise inverting it, incrementing without saturation, and decrementing without saturation.
4.1. PER-FRAGMENT OPERATIONS

For purposes of increment and decrement, the stencil bits are considered as an unsigned integer. Incrementing or decrementing with saturation clamps the stencil value at 0 and the maximum representable value. Incrementing or decrementing without saturation will wrap such that incrementing the maximum representable value results in 0, and decrementing 0 results in the maximum representable value.

The same symbolic values are given to indicate the stencil action if the depth buffer test (see section 4.1.6) fails (dpfail), or if it passes (dppass).

If the stencil test fails, the incoming fragment is discarded. The state required consists of the most recent values passed to StencilFunc or StencilFuncSeparate and to StencilOp or StencilOpSeparate, and a bit indicating whether stencil testing is enabled or disabled. In the initial state, stenciling is disabled, the front and back stencil reference value are both zero, the front and back stencil comparison functions are both ALWAYS, and the front and back stencil mask are both set to the value $2^s - 1$, where $s$ is greater than or equal to the number of bits in the deepest stencil buffer supported by the GL implementation. Initially, all three front and back stencil operations are KEEP.

If there is no stencil buffer, no stencil modification can occur, and it is as if the stencil tests always pass, regardless of any calls to StencilFunc.

4.1.6 Depth Buffer Test

The depth buffer test discards the incoming fragment if a depth comparison fails. The comparison is enabled or disabled with the generic Enable and Disable commands using the symbolic constant DEPTH_TEST. When disabled, the depth comparison and subsequent possible updates to the depth buffer value are bypassed and the fragment is passed to the next operation. The stencil value, however, is modified as indicated below as if the depth buffer test passed. If enabled, the comparison takes place and the depth buffer and stencil value may subsequently be modified.

The comparison is specified with

```c
void DepthFunc (enum func);
```

This command takes a single symbolic constant: one of NEVER, ALWAYS, LESS, LEQUAL, EQUAL, GREATER, GEQUAL, NOTEQUAL. Accordingly, the depth buffer test passes never, always, if the incoming fragment’s $z_w$ value is less than, less than or equal to, equal to, greater than, greater than or equal to, or not equal to the depth value stored at the location given by the incoming fragment’s $(x_w, y_w)$ coordinates.

If depth clamping (see section 2.22) is enabled, before the incoming fragment’s $z_w$ is compared $z_w$ is clamped to the range $[\min(n, f), \max(n, f)]$, where $n$ and $f$ are the current near and far depth range values (see section 2.16.1)
4.1. PER-FRAGMENT OPERATIONS

If the depth buffer test fails, the incoming fragment is discarded. The stencil value at the fragment’s \((x_w, y_w)\) coordinates is updated according to the function currently in effect for depth buffer test failure. Otherwise, the fragment continues to the next operation and the value of the depth buffer at the fragment’s \((x_w, y_w)\) location is set to the fragment’s \(z_w\) value. In this case the stencil value is updated according to the function currently in effect for depth buffer test success.

The necessary state is an eight-valued integer and a single bit indicating whether depth buffering is enabled or disabled. In the initial state the function is \texttt{LESS} and the test is disabled.

If there is no depth buffer, it is as if the depth buffer test always passes.

4.1.7 Occlusion Queries

Occlusion queries use query objects to track the number of fragments or samples that pass the depth test. An occlusion query can be started and finished by calling \texttt{BeginQuery} and \texttt{EndQuery}, respectively, with a \texttt{target} of \texttt{SAMPLES_PASSED}.

When an occlusion query is started, the samples-passed count maintained by the GL is set to zero. When an occlusion query is active, the samples-passed count is incremented for each fragment that passes the depth test. If the value of \texttt{SAMPLE_BUFFERS} is 0, then the samples-passed count is incremented by 1 for each fragment. If the value of \texttt{SAMPLE_BUFFERS} is 1, then the samples-passed count is incremented by the number of samples whose coverage bit is set. However, implementations, at their discretion, may instead increase the samples-passed count by the value of \texttt{SAMPLES} if any sample in the fragment is covered.

When an occlusion query finishes and all fragments generated by commands issued prior to \texttt{EndQuery} have been generated, the samples-passed count is written to the corresponding query object as the query result value, and the query result for that object is marked as available.

If the samples-passed count overflows (exceeds the value \(2^n - 1\), where \(n\) is the number of bits in the samples-passed count), its value becomes undefined. It is recommended, but not required, that implementations handle this overflow case by saturating at \(2^n - 1\) and incrementing no further.

The necessary state is a single bit indicating whether an occlusion query is active, the identifier of the currently active occlusion query, and a counter keeping track of the number of samples that have passed.

4.1.8 Blending

Blending combines the incoming \texttt{source} fragment’s R, G, B, and A values with the \texttt{destination} R, G, B, and A values stored in the framebuffer at the fragment’s
(x_w, y_w) location.

Source and destination values are combined according to the blend equation, quadruplets of source and destination weighting factors determined by the blend functions, and a constant blend color to obtain a new set of R, G, B, and A values, as described below.

If the color buffer is fixed-point, the components of the source and destination values and blend factors are clamped to [0, 1] prior to evaluating the blend equation. If the color buffer is floating-point, no clamping occurs. The resulting four values are sent to the next operation.

Blending applies only in RGBA mode; and only if the color buffer has a fixed-point or floating-point format. In color index mode, or if the color buffer has an integer format, proceed to the next operation.

Blending is enabled or disabled for an individual draw buffer with the commands

```c
void Enablei( enum target, uint index );
void Disablei( enum target, uint index );
```

target is the symbolic constant BLEND and index is an integer i specifying the draw buffer associated with the symbolic constant DRAW_BUFFERi. If the color buffer associated with DRAW_BUFFERi is one of FRONT, BACK, LEFT, RIGHT, or FRONT_–AND_BACK (specifying multiple color buffers), then the state enabled or disabled is applicable for all of the buffers. Blending can be enabled or disabled for all draw buffers using Enable or Disable with the symbolic constant BLEND. If blending is disabled for a particular draw buffer, or if logical operation on color values is enabled (section 4.1.11), proceed to the next operation.

An INVALID_VALUE error is generated if index is greater than the value of MAX_DRAW_BUFFERS minus one.

If multiple fragment colors are being written to multiple buffers (see section 4.2.1), blending is computed and applied separately for each fragment color and the corresponding buffer.

**Blend Equation**

Blending is controlled by the blend equations, defined by the commands

```c
void BlendEquation( enum mode );
void BlendEquationSeparate( enum modeRGB,  
                           enum modeAlpha );
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
4.1. PER-FRAGMENT OPERATIONS

BlendEquationSeparate argument modeRGB determines the RGB blend function while modeAlpha determines the alpha blend equation. BlendEquation argument mode determines both the RGB and alpha blend equations. modeRGB and modeAlpha must each be one of FUNC_ADD, FUNC_SUBTRACT, FUNC_REVERSE_SUBTRACT, MIN, or MAX.

Signed or unsigned normalized fixed-point destination (framebuffer) components are represented as described in section 2.1.5. Constant color components, floating-point destination components, and source (fragment) components are taken to be floating point values. If source components are represented internally by the GL as fixed-point values, they are also interpreted according to section 2.1.5.

Prior to blending, signed and unsigned normalized fixed-point color components undergo an implied conversion to floating-point using equations 2.1 and 2.3, respectively. This conversion must leave the values 0 and 1 invariant. Blending computations are treated as if carried out in floating-point.

If FRAMEBUFFER_SRGB is enabled and the value of FRAMEBUFFER_ATTACHMENT_COLOR_ENCODING for the framebuffer attachment corresponding to the destination buffer is SRGB (see section 6.1.3), the R, G, and B destination color values (after conversion from fixed-point to floating-point) are considered to be encoded for the sRGB color space and hence must be linearized prior to their use in blending. Each R, G, and B component is converted in the same fashion described for sRGB texture components in section 3.9.17.

If FRAMEBUFFER_SRGB is disabled or the value of FRAMEBUFFER_ATTACHMENT_COLOR_ENCODING is not SRGB, no linearization is performed.

The resulting linearized R, G, and B and unmodified A values are recombined as the destination color used in blending computations.

Table 4.1 provides the corresponding per-component blend equations for each mode, whether acting on RGB components for modeRGB or the alpha component for modeAlpha.

In the table, the s subscript on a color component abbreviation (R, G, B, or A) refers to the source color component for an incoming fragment, the d subscript on a color component abbreviation refers to the destination color component at the corresponding framebuffer location, and the c subscript on a color component abbreviation refers to the constant blend color component. A color component abbreviation without a subscript refers to the new color component resulting from blending. Additionally, \(S_r, S_g, S_b,\) and \(S_a\) are the red, green, blue, and alpha components of the source weighting factors determined by the source blend function, and \(D_r, D_g, D_b,\) and \(D_a\) are the red, green, blue, and alpha components of the destination weighting factors determined by the destination blend function. Blend functions are described below.

Table 4.1: RGB and alpha blend equations.

**Blend Functions**

The weighting factors used by the blend equation are determined by the blend functions. Blend functions are specified with the commands

```c
void BlendFuncSeparate(enum srcRGB, enum dstRGB, 
                       enum srcAlpha, enum dstAlpha);
void BlendFunc(enum src, enum dst);
```

`BlendFuncSeparate` arguments `srcRGB` and `dstRGB` determine the source and destination RGB blend functions, respectively, while `srcAlpha` and `dstAlpha` determine the source and destination alpha blend functions. `BlendFunc` argument `src` determines both RGB and alpha source functions, while `dst` determines both RGB and alpha destination functions.

The possible source and destination blend functions and their corresponding computed blend factors are summarized in table 4.2.

**Blend Color**

The constant color \( C_c \) to be used in blending is specified with the command

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
4.1. PER-FRAGMENT OPERATIONS

void BlendColor(clampf red, clampf green, clampf blue, clampf alpha);

The constant color can be used in both the source and destination blending functions.

The state required for blending is two integers for the RGB and alpha blend equations, four integers indicating the source and destination RGB and alpha blending functions, four floating-point values to store the RGBA constant blend color, and a bit indicating whether blending is enabled or disabled for each of the MAX_DRAW_BUFFERS draw buffers.

The initial blend equations for RGB and alpha are both FUNC_ADD. The initial blending functions are ONE for the source RGB and alpha functions and ZERO for the destination RGB and alpha functions. The initial constant blend color is (R, G, B, A) = (0, 0, 0, 0). Initially, blending is disabled for all draw buffers.

The value of the blend enable for draw buffer $i$ can be queried by calling IsEnabled with target BLEND and index $i$. The value of the blend enable for draw buffer zero may also be queried by calling IsEnabled with value BLEND.

Blending occurs once for each color buffer currently enabled for blending and for writing (section 4.2.1) using each buffer’s color for $C_d$. If a color buffer has no A value, then $A_d$ is taken to be 1.

4.1.9 sRGB Conversion

If FRAMEBUFFER_SRGB is enabled and the value of FRAMEBUFFER_ATTACHMENT_COLOR_ENCODING for the framebuffer attachment corresponding to the destination buffer is SRGB (see section 6.1.3), the R, G, and B values after blending are converted into the non-linear sRGB color space by computing

$$c_s = \begin{cases} 
0.0, & c_l \leq 0 \\
12.92c_l, & 0 < c_l < 0.0031308 \\
1.055c_l^{0.41666} - 0.055, & 0.0031308 \leq c_l < 1 \\
1.0, & c_l \geq 1 
\end{cases}$$

(4.1)

where $c_l$ is the R, G, or B element and $c_s$ is the result (effectively converted into an sRGB color space).

If FRAMEBUFFER_ATTACHMENT_COLOR_ENCODING is not SRGB, then

$$c_s = c_l.$$

The resulting $c_s$ values for R, G, and B, and the unmodified A form a new RGBA color value. If the color buffer is fixed-point, each component is clamped.
to the range \([0, 1]\) and then converted to a fixed-point value using equation 2.4. The resulting four values are sent to the subsequent dithering operation.

### 4.1.10 Dithering

Dithering selects between two representable color values or indices. A representable value is a value that has an exact representation in the color buffer. In RGBA mode dithering selects, for each color component, either the largest representable color value (for that particular color component) that is less than or equal to the incoming color component value, \(c\), or the smallest representable color value that is greater than or equal to \(c\). The selection may depend on the \(x_w\) and \(y_w\) coordinates of the pixel, as well as on the exact value of \(c\). If one of the two values does not exist, then the selection defaults to the other value.

In color index mode dithering selects either the largest representable index that is less than or equal to the incoming color value, \(c\), or the smallest representable index that is greater than or equal to \(c\). If one of the two indices does not exist, then the selection defaults to the other value.

Many dithering selection algorithms are possible, but an individual selection must depend only on the incoming color index or component value and the fragment’s \(x\) and \(y\) window coordinates. If dithering is disabled, then each incoming color component \(c\) is replaced with the largest positive representable color value (for that particular component) that is less than or equal to \(c\), or by the smallest negative representable value, if no representable value is less than or equal to \(c\). A color index is rounded to the nearest representable index value.

Dithering is enabled with `Enable` and disabled with `Disable` using the symbolic constant `DITHER`. The state required is thus a single bit. Initially, dithering is enabled.

### 4.1.11 Logical Operation

Finally, a logical operation is applied between the incoming fragment’s color or index values and the color or index values stored at the corresponding location in the framebuffer. The result replaces the values in the framebuffer at the fragment’s \((x_w, y_w)\) coordinates. If the selected draw buffers refer to the same framebuffer-attachable image more than once, then the values stored in that image are undefined.

The logical operation on color indices is enabled or disabled with `Enable` or `Disable` using the symbolic constant `INDEX_LOGIC_OP`. (For compatibility with GL version 1.0, the symbolic constant `LOGIC_OP` may also be used.) The logical operation on color values is enabled or disabled with `Enable` or `Disable` using...

Table 4.3: Arguments to `LogicOp` and their corresponding operations.

the symbolic constant `COLOR_LOGIC_OP`. If the logical operation is enabled for color values, it is as if blending were disabled, regardless of the value of `BLEND`. If multiple fragment colors are being written to multiple buffers (see section 4.2.1), the logical operation is computed and applied separately for each fragment color and the corresponding buffer.

Logical operation has no effect on a floating-point destination color buffer. However, if logical operation is enabled, blending is still disabled.

The logical operation is selected by

```c
void LogicOp(enum op);
```

*op* is a symbolic constant; the possible constants and corresponding operations are enumerated in table 4.3. In this table, *s* is the value of the incoming fragment and *d* is the value stored in the framebuffer. The numeric values assigned to the symbolic constants are the same as those assigned to the corresponding symbolic values in the X window system.

Logical operations are performed independently for each color index buffer that is selected for writing, or for each red, green, blue, and alpha value of each color buffer that is selected for writing. The required state is an integer indicating...
the logical operation, and two bits indicating whether the logical operation is enabled or disabled. The initial state is for the logic operation to be given by COPY, and to be disabled.

4.1.12 Additional Multisample Fragment Operations

If the DrawBuffer mode is NONE, no change is made to any multisample or color buffer. Otherwise, fragment processing is as described below.

If MULTISAMPLE is enabled, and the value of SAMPLE_BUFFERS is one, the alpha test, stencil test, depth test, blending, dithering, and logical operations are performed for each pixel sample, rather than just once for each fragment. Failure of the alpha, stencil, or depth test results in termination of the processing of that sample, rather than discarding of the fragment. All operations are performed on the color, depth, and stencil values stored in the multisample buffer (to be described in a following section). The contents of the color buffers are not modified at this point.

Stencil, depth, blending, dithering, and logical operations are performed for a pixel sample only if that sample’s fragment coverage bit is a value of 1. If the corresponding coverage bit is 0, no operations are performed for that sample.

If MULTISAMPLE is disabled, and the value of SAMPLE_BUFFERS is one, the fragment may be treated exactly as described above, with optimization possible because the fragment coverage must be set to full coverage. Further optimization is allowed, however. An implementation may choose to identify a centermost sample, and to perform alpha, stencil, and depth tests on only that sample. Regardless of the outcome of the stencil test, all multisample buffer stencil sample values are set to the appropriate new stencil value. If the depth test passes, all multisample buffer depth sample values are set to the depth of the fragment’s centermost sample’s depth value, and all multisample buffer color sample values are set to the color value of the incoming fragment. Otherwise, no change is made to any multisample buffer color or depth value.

After all operations have been completed on the multisample buffer, the sample values for each color in the multisample buffer are combined to produce a single color value, and that value is written into the corresponding color buffers selected by DrawBuffer or DrawBuffers. An implementation may defer the writing of the color buffers until a later time, but the state of the framebuffer must behave as if the color buffers were updated as each fragment was processed. The method of combination is not specified. If the framebuffer contains sRGB values, then it is recommended that the an average of sample values is computed in a linearized space, as for blending (see section 4.1.8). Otherwise, a simple average computed independently for each color component is recommended.
4.2 Whole Framebuffer Operations

The preceding sections described the operations that occur as individual fragments are sent to the framebuffer. This section describes operations that control or affect the whole framebuffer.

4.2.1 Selecting a Buffer for Writing

The first such operation is controlling the color buffers into which each of the fragment color values is written. This is accomplished with either DrawBuffer or DrawBuffers.

The command

```c
void DrawBuffer( enum buf );
```

defines the set of color buffers to which fragment color zero is written. `buf` must be one of the values from tables 4.4 or 4.5. In addition, acceptable values for `buf` depend on whether the GL is using the default framebuffer (i.e., DRAW_FRAMEBUFFER_BINDING is zero), or a framebuffer object (i.e., DRAW_FRAMEBUFFER_BINDING is non-zero). In the initial state, the GL is bound to the default framebuffer. For more information about framebuffer objects, see section 4.4.

If the GL is bound to the default framebuffer, then `buf` must be one of the values listed in table 4.4, which summarizes the constants and the buffers they indicate. In this case, `buf` is a symbolic constant specifying zero, one, two, or four buffers for writing. These constants refer to the four potentially visible buffers (front left, front right, back left, and back right), and to the auxiliary buffers. Arguments other than `AUXi` that omit reference to `LEFT` or `RIGHT` refer to both left and right buffers. Arguments other than `AUXi` that omit reference to `FRONT` or `BACK` refer to both front and back buffers. `AUXi` enables drawing only to auxiliary buffer `i`. Each `AUXi` adheres to `AUXi = AUX0 + i`, and `i` must be in the range 0 to the value of `AUX_BUFFERS` minus one.

If the GL is bound to a framebuffer object, `buf` must be one of the values listed in table 4.5, which summarizes the constants and the buffers they indicate. In this case, `buf` is a symbolic constant specifying a single color buffer for writing. Specifying `COLOR_ATTACHMENTi` enables drawing only to the image attached to the framebuffer at `COLOR_ATTACHMENTi`. Each `COLOR_ATTACHMENTi` adheres to `COLOR_ATTACHMENTi = COLOR_ATTACHMENT0 + i`. The initial value of `DRAW_BUFFER` for framebuffer objects is `COLOR_ATTACHMENT0`.

OpenGL 3.2 (Compatibility Profile) - December 7, 2009

Table 4.6: Arguments to DrawBuffers when the context is bound to the default framebuffer, and the buffers they indicate.

NONE.

The command

```c
void DrawBuffers(sizei n, const enum *bufs);
```

defines the draw buffers to which all fragment colors are written. `n` specifies the number of buffers in `bufs`. `bufs` is a pointer to an array of symbolic constants specifying the buffer to which each fragment color is written.

Each buffer listed in `bufs` must be one of the values from tables 4.5 or 4.6. Otherwise, an INVALID_ENUM error is generated. Further, acceptable values for the constants in `bufs` depend on whether the GL is using the default framebuffer (i.e., DRAW_FRAMEBUFFER_BINDING is zero), or a framebuffer object (i.e., DRAW_FRAMEBUFFER_BINDING is non-zero). For more information about framebuffer objects, see section 4.4.

If the GL is bound to the default framebuffer, then each of the constants must be one of the values listed in table 4.6.

If the GL is bound to a framebuffer object, then each of the constants must be one of the values listed in table 4.5.

In both cases, the draw buffers being defined correspond in order to the respective fragment colors. The draw buffer for fragment colors beyond `n` is set to NONE.

The maximum number of draw buffers is implementation-dependent. The number of draw buffers supported can be queried by calling GetIntegerv with the symbolic constant MAX_DRAW_BUFFERS. An INVALID_VALUE error is generated if `n` is greater than MAX_DRAW_BUFFERS.

Except for NONE, a buffer may not appear more than once in the array pointed
4.2. WHOLE FRAMEBUFFER OPERATIONS

to by *bufs*. Specifying a buffer more than once will result in the error **INVALID_OPERATION**.

If fixed-function fragment shading is being performed, **DrawBuffers** specifies a set of draw buffers into which the fragment color is written.

If a fragment shader writes to *gl_FragColor*, **DrawBuffers** specifies a set of draw buffers into which the single fragment color defined by *gl_FragColor* is written. If a fragment shader writes to *gl_FragData*, or a user-defined varying out variable, **DrawBuffers** specifies a set of draw buffers into which each of the multiple output colors defined by these variables are separately written. If a fragment shader writes to none of *gl_FragColor*, *gl_FragData*, nor any user-defined varying out variables, the values of the fragment colors following shader execution are undefined, and may differ for each fragment color.

For both the default framebuffer and framebuffer objects, the constants **FRONT**, **BACK**, **LEFT**, **RIGHT**, and **FRONT_AND_BACK** are not valid in the *bufs* array passed to **DrawBuffers**, and will result in the error **INVALID_ENUM**. This restriction is because these constants may themselves refer to multiple buffers, as shown in table 4.4.

If the GL is bound to the default framebuffer and **DrawBuffers** is supplied with a constant (other than **NONE**) that does not indicate any of the color buffers allocated to the GL context by the window system, the error **INVALID_OPERATION** will be generated.

If the GL is bound to a framebuffer object and **DrawBuffers** is supplied with a constant from table 4.6, or **COLOR_ATTACHMENTm** where *m* is greater than or equal to the value of **MAX_COLOR_ATTACHMENTS**, then the error **INVALID_OPERATION** results.

Indicating a buffer or buffers using **DrawBuffer** or **DrawBuffers** causes subsequent pixel color value writes to affect the indicated buffers.

Specifying **NONE** as the draw buffer for a fragment color will inhibit that fragment color from being written to any buffer.

Monoscopic contexts include only left buffers, while stereoscopic contexts include both left and right buffers. Likewise, single buffered contexts include only front buffers, while double buffered contexts include both front and back buffers. The type of context is selected at GL initialization.

The state required to handle color buffer selection for each framebuffer is an integer for each supported fragment color. For the default framebuffer, in the initial state the draw buffer for fragment color zero is **BACK** if there is a back buffer; **FRONT** if there is no back buffer; and **NONE** if no default framebuffer is associated with the context. For framebuffer objects, in the initial state the draw buffer for fragment color zero is **COLOR_ATTACHMENT0**. For both the default framebuffer and framebuffer objects, the initial state of draw buffers for fragment colors other
4.2. WHOLE FRAMEBUFFER OPERATIONS

then zero is NONE.

The value of the draw buffer selected for fragment color \( i \) can be queried by calling \texttt{GetIntegerv} with the symbolic constant \texttt{DRAW_BUFFER}\(_i\). \texttt{DRAW_BUFFER} is equivalent to \texttt{DRAW_BUFFER0}.

4.2.2 Fine Control of Buffer Updates

Writing of bits to each of the logical framebuffers after all per-fragment operations have been performed may be masked. The commands

```c
void IndexMask( uint mask );
void ColorMask( boolean r, boolean g, boolean b, boolean a );
void ColorMaski( uint buf, boolean r, boolean g, boolean b, boolean a );
```

control writes to the active draw buffers.

The least significant \( n \) bits of \texttt{mask}, where \( n \) is the number of bits in a color index buffer, specify a mask. Where a 1 appears in this mask, the corresponding bit in the color index buffer (or buffers) is written; where a 0 appears, the bit is not written. This mask applies only in color index mode.

In RGBA mode, \texttt{ColorMask} and \texttt{ColorMaski} are used to mask the writing of R, G, B and A values to the draw buffer or buffers. \texttt{ColorMaski} sets the mask for a particular draw buffer. The mask for \texttt{DRAW_BUFFER}\(_i\) is modified by passing \( i \) as the parameter \texttt{buf}: \( r, g, b, \) and \( a \) indicate whether R, G, B, or A values, respectively, are written or not (a value of \texttt{TRUE} means that the corresponding value is written). The mask specified by \( r, g, b, \) and \( a \) is applied to the color buffer associated with \texttt{DRAW_BUFFER}\(_i\). If \texttt{DRAW_BUFFER}\(_i\) is one of \texttt{FRONT}, \texttt{BACK}, \texttt{LEFT}, \texttt{RIGHT}, or \texttt{FRONT_AND_BACK} (specifying multiple color buffers) then the mask is applied to all of the buffers.

\texttt{ColorMask} sets the mask for all draw buffers to the same values as specified by \( r, g, b, \) and \( a \).

An \texttt{INVALID_VALUE} error is generated if \texttt{index} is greater than the value of \texttt{MAX_DRAW_BUFFERS} minus one.

In the initial state, all bits (in color index mode) and all color values (in RGBA mode) are enabled for writing for all draw buffers.

The value of the color writemask for draw buffer \( i \) can be queried by calling \texttt{GetBooleani_v} with \texttt{target} \texttt{COLOR_WRITEMASK} and \texttt{index} \( i \). The value of the color writemask for draw buffer zero may also be queried by calling \texttt{GetBooleanv} with \texttt{value} \texttt{COLOR_WRITEMASK}.

The depth buffer can be enabled or disabled for writing \( z_w \) values using

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
4.2. WHOLE FRAMEBUFFER OPERATIONS

void DepthMask(boolean mask);

If mask is non-zero, the depth buffer is enabled for writing; otherwise, it is disabled. In the initial state, the depth buffer is enabled for writing.

The commands

void StencilMask(uint mask);
void StencilMaskSeparate(enum face, uint mask);

control the writing of particular bits into the stencil planes.

The least significant \( s \) bits of mask, where \( s \) is the number of bits in the stencil buffer, specify an integer mask. Where a 1 appears in this mask, the corresponding bit in the stencil buffer is written; where a 0 appears, the bit is not written. The face parameter of StencilMaskSeparate can be FRONT, BACK, or FRONT_AND_BACK and indicates whether the front or back stencil mask state is affected. StencilMask sets both front and back stencil mask state to identical values.

Fragments generated by front-facing primitives use the front mask and fragments generated by back-facing primitives use the back mask (see section 4.1.5). The clear operation always uses the front stencil write mask when clearing the stencil buffer.

The state required for the various masking operations is an integer for color indices, two integers for the front and back stencil values, and a bit for depth values. A set of four bits is also required indicating which color components of an RGBA value should be written. In the initial state, the integer masks are all ones, as are the bits controlling depth value and RGBA component writing.

Fine Control of Multisample Buffer Updates

When the value of SAMPLE_BUFFERS is one, ColorMask, DepthMask, and StencilMask or StencilMaskSeparate control the modification of values in the multisample buffer. The color mask has no effect on modifications to the color buffers. If the color mask is entirely disabled, the color sample values must still be combined (as described above) and the result used to replace the color values of the buffers enabled by DrawBuffer.

4.2.3 Clearing the Buffers

The GL provides a means for setting portions of every pixel in a particular buffer to the same value. The argument to

void Clear(bitfield buf);

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
is zero or the bitwise OR of one or more values indicating which buffers are to be cleared. The values are \texttt{COLOR\_BUFFER\_BIT}, \texttt{ACCUM\_BUFFER\_BIT}, \texttt{DEPTH\_BUFFER\_BIT}, and \texttt{STENCIL\_BUFFER\_BIT}, indicating the buffers currently enabled for color writing, the accumulation buffer, the depth buffer, and the stencil buffer (see below), respectively. The value to which each buffer is cleared depends on the setting of the clear value for that buffer. If \texttt{buf} is zero, no buffers are cleared. If \texttt{buf} contains any bits other than \texttt{COLOR\_BUFFER\_BIT}, \texttt{ACCUM\_BUFFER\_BIT}, \texttt{DEPTH\_BUFFER\_BIT}, or \texttt{STENCIL\_BUFFER\_BIT}, then the error \texttt{INVALID\_VALUE} is generated.

\begin{verbatim}
void ClearColor( clampf r, clampf g, clampf b,
clampf a );
\end{verbatim}

sets the clear value for fixed- and floating-point color buffers in RGBA mode. The specified components are stored as floating-point values.

The command

\begin{verbatim}
void ClearIndex( float index );
\end{verbatim}

sets the clear color index. \texttt{index} is converted to a fixed-point value with unspecified precision to the left of the binary point; the integer part of this value is then masked with $2^m - 1$, where \texttt{m} is the number of bits in a color index value stored in the framebuffer.

The command

\begin{verbatim}
void ClearDepth( clamped d );
\end{verbatim}

sets the depth value used when clearing the depth buffer. \texttt{d} is clamped to the range $[0, 1]$. When clearing a fixed-point depth buffer, \texttt{d} is converted to fixed-point according to the rules for a window \texttt{z} value given in section 2.16.1. No conversion is applied when clearing a floating-point depth buffer.

The command

\begin{verbatim}
void ClearStencil( int s );
\end{verbatim}

takes a single integer argument that is the value to which to clear the stencil buffer. \texttt{s} is masked to the number of bitplanes in the stencil buffer.

The command

\begin{verbatim}
void ClearAccum( float r, float g, float b, float a );
\end{verbatim}
4.2. WHOLE FRAMEBUFFER OPERATIONS

takes four floating-point arguments that are the values, in order, to which to set the R, G, B, and A values of the accumulation buffer (see the next section). These values are clamped to the range \([-1, 1]\) when they are specified.

When \texttt{Clear} is called, the only per-fragment operations that are applied (if enabled) are the pixel ownership test, the scissor test, and dithering. The masking operations described in section 4.2.2 are also applied. If a buffer is not present, then a \texttt{Clear} directed at that buffer has no effect. Unsigned normalized fixed-point and signed normalized fixed-point RGBA color buffers are cleared to color values derived by clamping each component of the clear color to the range \([0, 1]\) or \([-1, 1]\) respectively, then converting to fixed-point using equations 2.4 or 2.6, respectively. The result of clearing integer color buffers is undefined.

The state required for clearing is a clear value for each of the color buffer, the accumulation buffer, the depth buffer, and the stencil buffer. Initially, the RGBA color clear value is \((0, 0, 0, 0)\), the accumulation buffer clear value is \((0, 0, 0, 0)\), the clear color index is 0, the depth buffer clear value is 1.0, and the stencil buffer clear index is 0.

Individual buffers of the currently bound draw framebuffer may be cleared with the command

\[
\texttt{void ClearBuffer\{if ui\}v(enum buffer, int drawbuffer, const T *value);} \]

where \texttt{buffer} and \texttt{drawbuffer} identify a buffer to clear, and \texttt{value} specifies the value or values to clear it to.

If \texttt{buffer} is \texttt{COLOR}, a particular draw buffer \texttt{DRAW\_BUFFER\_i} is specified by passing \(i\) as the parameter \texttt{drawbuffer}, and \texttt{value} points to a four-element vector specifying the R, G, B, and A color to clear that draw buffer to. If the draw buffer is one of \texttt{FRONT}, \texttt{BACK}, \texttt{LEFT}, \texttt{RIGHT}, or \texttt{FRONT\_AND\_BACK}, identifying multiple buffers, each selected buffer is cleared to the same value. The \texttt{ClearBufferfv}, \texttt{ClearBufferiv}, and \texttt{ClearBufferuiv} commands should be used to clear fixed- and floating-point, signed integer, and unsigned integer color buffers respectively. Clamping and conversion for fixed-point color buffers are performed in the same fashion as \texttt{ClearColor}.

If \texttt{buffer} is \texttt{DEPTH}, \texttt{drawbuffer} must be zero, and \texttt{value} points to the single depth value to clear the depth buffer to. Clamping and type conversion for fixed-point depth buffers are performed in the same fashion as \texttt{ClearDepth}. Only \texttt{ClearBufferfv} should be used to clear depth buffers.

If \texttt{buffer} is \texttt{STENCIL}, \texttt{drawbuffer} must be zero, and \texttt{value} points to the single stencil value to clear the stencil buffer to. Masking and type conversion are performed in the same fashion as \texttt{ClearStencil}. Only \texttt{ClearBufferiv} should be used to clear stencil buffers.
The command

```c
void ClearBufferfi(enum buffer, int drawbuffer,
                  float depth, int stencil);
```
clears both depth and stencil buffers of the currently bound draw framebuffer. `buffer` must be `DEPTH_STENCIL` and `drawbuffer` must be zero. `depth` and `stencil` are the values to clear the depth and stencil buffers to, respectively. Clamping and type conversion of `depth` for fixed-point depth buffers is performed in the same fashion as `ClearDepth`. Masking of `stencil` for stencil buffers is performed in the same fashion as `ClearStencil`. `ClearBufferfi` is equivalent to clearing the depth and stencil buffers separately, but may be faster when a buffer of internal format `DEPTH_STENCIL` is being cleared.

The result of `ClearBuffer` is undefined if no conversion between the type of the specified `value` and the type of the buffer being cleared is defined (for example, if `ClearBufferiv` is called for a fixed- or floating-point buffer, or if `ClearBufferfv` is called for a signed or unsigned integer buffer). This is not an error.

When `ClearBuffer` is called, the same per-fragment and masking operations defined for `Clear` are applied.

**Errors**

- `ClearBuffer{if ui}v` generates an `INVALID_ENUM` error if `buffer` is not `COLOR`, `DEPTH`, or `STENCIL`. `ClearBufferfi` generates an `INVALID_ENUM` error if `buffer` is not `DEPTH_STENCIL`.
- `ClearBuffer` generates an `INVALID_VALUE` error if `buffer` is `COLOR` and `drawbuffer` is less than zero, or greater than the value of `MAX_DRAW_BUFFERS` minus one; or if `buffer` is `DEPTH`, `STENCIL`, or `DEPTH_STENCIL` and `drawbuffer` is not zero.
- `ClearBuffer` generates an `INVALID_OPERATION` error if `buffer` is `COLOR` and the GL is in color index mode.

**Clearing the Multisample Buffer**

The color samples of the multisample buffer are cleared when one or more color buffers are cleared, as specified by the `Clear` mask bit `COLOR_BUFFER_BIT` and the `DrawBuffer` mode. If the `DrawBuffer` mode is `NONE`, the color samples of the multisample buffer cannot be cleared using `Clear`.

If the `Clear` mask bits `DEPTH_BUFFER_BIT` or `STENCIL_BUFFER_BIT` are set, then the corresponding depth or stencil samples, respectively, are cleared.

The `ClearBuffer` commands also clear color, depth, or stencil samples of multisample buffers corresponding to the specified buffer.
4.2. WHOLE FRAMEBUFFER OPERATIONS

4.2.4 The Accumulation Buffer

Each portion of a pixel in the accumulation buffer consists of four values: one for each of R, G, B, and A. The accumulation buffer is controlled exclusively through the use of

```c
void Accum(enum op, float value);
```

(except for clearing it). `op` is a symbolic constant indicating an accumulation buffer operation, and `value` is a floating-point value to be used in that operation. The possible operations are `ACCUM`, `LOAD`, `RETURN`, `MULT`, and `ADD`.

When the scissor test is enabled (section 4.1.2), then only those pixels within the current scissor box are updated by any `Accum` operation; otherwise, all pixels in the window are updated. The accumulation buffer operations apply identically to every affected pixel, so we describe the effect of each operation on an individual pixel. Accumulation buffer values are taken to be signed values in the range \([-1, 1]\). Using `ACCUM` obtains R, G, B, and A components from the buffer currently selected for reading (section 4.3.2). If the color buffer is fixed-point, each component is considered as an unsigned normalized value in the range \([0, 1]\) and is converted to floating-point using equation 2.1. Each result is then multiplied by `value`. The results of this multiplication are then added to the corresponding color component currently in the accumulation buffer, and the resulting color value replaces the current accumulation buffer color value.

The `LOAD` operation has the same effect as `ACCUM`, but the computed values replace the corresponding accumulation buffer components rather than being added to them.

The `RETURN` operation takes each color value from the accumulation buffer, multiplies each of the R, G, B, and A components by `value`. If fragment color clamping is enabled, the results are then clamped to the range \([0, 1]\). The resulting color value is placed in the buffers currently enabled for color writing as if it were a fragment produced from rasterization, except that the only per-fragment operations that are applied (if enabled) are the pixel ownership test, the scissor test (section 4.1.2), and dithering (section 4.1.10). Color masking (section 4.2.2) is also applied.

The `MULT` operation multiplies each R, G, B, and A in the accumulation buffer by `value` and then returns the scaled color components to their corresponding accumulation buffer locations. `ADD` is the same as `MULT` except that `value` is added to each of the color components.

The color components operated on by `Accum` must be clamped only if the operation is `RETURN`. In this case, a value sent to the enabled color buffers is first
4.3. DRAWING, READING, AND COPYING PIXELS

clamped to \([0, 1]\). Otherwise, results are undefined if the result of an operation on a color component is out of the range \([-1, 1]\).

If there is no accumulation buffer; if the DRAW_FRAMEBUFFER and READ_FRAMEBUFFER bindings (see section 4.4.4) do not refer to the same object; or if the GL is in color index mode, Accum generates the error INVALID_OPERATION.

No state (beyond the accumulation buffer itself) is required for accumulation buffering.

4.3 Drawing, Reading, and Copying Pixels

Pixels may be written to the framebuffer using DrawPixels. Pixels may be read from the framebuffer using ReadPixels. CopyPixels and BlitFramebuffer can be used to copy a block of pixels from one portion of the framebuffer to another.

4.3.1 Writing to the Stencil or Depth/Stencil Buffers

The operation of DrawPixels was described in section 3.7.5, except if the format argument was STENCIL_INDEX or DEPTH_STENCIL. In this case, all operations described for DrawPixels take place, but window \((x, y)\) coordinates, each with the corresponding stencil index, or depth value and stencil index, are produced in lieu of fragments. Each coordinate-data pair is sent directly to the per-fragment operations, bypassing the texture, fog, and antialiasing application stages of rasterization. Each pair is then treated as a fragment for purposes of the pixel ownership and scissor tests; all other per-fragment operations are bypassed. Finally, each stencil index is written to its indicated location in the framebuffer, subject to the current front stencil mask (set with StencilMask or StencilMaskSeparate). If a depth component is present, and the setting of DepthMask is not FALSE, it is also written to the framebuffer; the setting of DepthFunc is ignored.

The error INVALID_OPERATION results if the format argument is STENCIL_INDEX and there is no stencil buffer, or if format is DEPTH_STENCIL and there is not both a depth buffer and a stencil buffer.

4.3.2 Reading Pixels

The method for reading pixels from the framebuffer and placing them in pixel pack buffer or client memory is diagrammed in figure 4.2. We describe the stages of the pixel reading process in the order in which they occur.

Initially, zero is bound for the PIXEL_PACK_BUFFER, indicating that image read and query commands such as ReadPixels return pixel results into client memory pointer parameters. However, if a non-zero buffer object is bound as the current
Figure 4.2. Operation of **ReadPixels**. Operations in dashed boxes may be enabled or disabled, except in the case of "convert RGB to L", which is only applied when reading color data in luminosity formats. RGBA and color index pixel paths are shown; depth and stencil pixel paths are not shown.

Table 4.7: PixelStore parameters pertaining to ReadPixels, GetColorTable, GetConvolutionFilter, GetSeparableFilter, GetHistogram, GetMinmax, GetPolygonStipple, and GetTexImage.

Pixels are read using

```c
void ReadPixels( int x, int y, sizei width, sizei height,
                  enum format, enum type, void *data );
```

The arguments after x and y to `ReadPixels` are described in section 3.7.4. The pixel storage modes that apply to `ReadPixels` and other commands that query images (see section 6.1) are summarized in table 4.7.

`ReadPixels` generates an INVALID_OPERATION error if READ_FRAMEBUFFER_BINDING (see section 4.4) is non-zero, the read framebuffer is framebuffer complete, and the value of SAMPLE_BUFFERS for the read framebuffer is greater than zero.

**Obtaining Pixels from the Framebuffer**

If the `format` is DEPTH_COMPONENT, then values are obtained from the depth buffer. If there is no depth buffer, the error INVALID_OPERATION occurs.

If there is a multisample buffer (the value of SAMPLE_BUFFERS is one), then values are obtained from the depth samples in this buffer. It is recommended that the depth value of the centermost sample be used, though implementations may choose any function of the depth sample values at each pixel.

If the `format` is DEPTH_STENCIL, then values are taken from both the depth buffer and the stencil buffer. If there is no depth buffer or if there is no stencil...
4.3. **DRAWING, READING, AND COPYING PIXELS**

buffer, then the error `INVALID_OPERATION` occurs. If the `type` parameter is not `UNSIGNED_INT_24_8` or `FLOAT_32_UNSIGNED_INT_24_8_REV`, then the error `INVALID_ENUM` occurs.

If there is a multisample buffer, then values are obtained from the depth and stencil samples in this buffer. It is recommended that the depth and stencil values of the centermost sample be used, though implementations may choose any function of the depth and stencil sample values at each pixel.

If the `format` is `STENCIL_INDEX`, then values are taken from the stencil buffer; again, if there is no stencil buffer, the error `INVALID_OPERATION` occurs.

If there is a multisample buffer, then values are obtained from the stencil samples in this buffer. It is recommended that the stencil value of the centermost sample be used, though implementations may choose any function of the stencil sample values at each pixel.

For all other formats, the *read buffer* from which values are obtained is one of the color buffers; the selection of color buffer is controlled with `ReadBuffer`.

The command

```c
void ReadBuffer( enum src );
```

takes a symbolic constant as argument. `src` must be one of the values from tables 4.4 or 4.5. Otherwise, an `INVALID_ENUM` error is generated. Further, the acceptable values for `src` depend on whether the GL is using the default framebuffer (i.e., `READ_FRAMEBUFFER_BINDING` is zero), or a framebuffer object (i.e., `READ_FRAMEBUFFER_BINDING` is non-zero). For more information about framebuffer objects, see section 4.4.

If the object bound to `READ_FRAMEBUFFER_BINDING` is not `framebuffer complete` (as defined in section 4.4.4), then `ReadPixels` generates the error `INVALID_FRAMEBUFFER_OPERATION`. If `ReadBuffer` is supplied with a constant that is neither legal for the default framebuffer, nor legal for a framebuffer object, then the error `INVALID_ENUM` results.

When `READ_FRAMEBUFFER_BINDING` is zero, i.e. the default framebuffer, `src` must be one of the values listed in table 4.4, including `NONE`, `FRONT_AND_BACK`, `FRONT`, and `LEFT` refer to the front left buffer, `BACK` refers to the back left buffer, and `RIGHT` refers to the front right buffer. The other constants correspond directly to the buffers that they name. If the requested buffer is missing, then the error `INVALID_OPERATION` is generated. For the default framebuffer, the initial setting for `ReadBuffer` is `FRONT` if there is no back buffer and `BACK` otherwise.

When the GL is using a framebuffer object, `src` must be one of the values listed in table 4.5, including `NONE`. In a manner analogous to how the `DRAW_BUFFERS` state is handled, specifying `COLOR_ATTACHMENTi` enables reading from the image...
attached to the framebuffer at COLOR_ATTACHMENT\textsubscript{i}. For framebuffer objects, the initial setting for \texttt{ReadBuffer} is COLOR_ATTACHMENT\textsubscript{0}.

\texttt{ReadPixels} generates an \texttt{INVALID_OPERATION} error if it attempts to select a color buffer while \texttt{READ_BUFFER} is \texttt{NONE}.

\texttt{ReadPixels} obtains values from the selected buffer from each pixel with lower left hand corner at \((x + i, y + j)\) for \(0 \leq i < \text{width}\) and \(0 \leq j < \text{height}\); this pixel is said to be the \(i\)th pixel in the \(j\)th row. If any of these pixels lies outside of the window allocated to the current GL context, or outside of the image attached to the currently bound framebuffer object, then the values obtained for those pixels are undefined. When \texttt{READ_FRAMEBUFFER_BINDING} is zero, values are also undefined for individual pixels that are not owned by the current context. Otherwise, \texttt{ReadPixels} obtains values from the selected buffer, regardless of how those values were placed there.

If the GL is in RGBA mode, and \texttt{format} is one of LUMINANCE, LUMINANCE\_\_ALPHA, RED, GREEN, BLUE, ALPHA, RG, RGB, RGBA, BGR, or BGRA, then red, green, blue, and alpha values are obtained from the selected buffer at each pixel location. If the framebuffer does not support alpha values then the A that is obtained is 1.0. If \texttt{format} is COLOR\_INDEX and the GL is in RGBA mode then the error \texttt{INVALID_OPERATION} occurs. If the GL is in color index mode, and \texttt{format} is not DEPTH\_COMPONENT, DEPTH\_STENCIL, or STENCIL\_INDEX, then the color index is obtained at each pixel location.

If \texttt{format} is an integer format and the color buffer is not an integer format; if the color buffer is an integer format and \texttt{format} is not an integer format; or if \texttt{format} is an integer format and \texttt{type} is FLOAT or HALF\_FLOAT, the error \texttt{INVALID\_OPERATION} occurs.

When \texttt{READ_FRAMEBUFFER_BINDING} is non-zero, the red, green, blue, and alpha values are obtained by first reading the internal component values of the corresponding value in the image attached to the selected logical buffer. Internal components are converted to an RGBA color by taking each R, G, B, and A component present according to the base internal format of the buffer (as shown in table 3.16). If G, B, or A values are not present in the internal format, they are taken to be zero, zero, and one respectively.

Conversion of RGBA values

This step applies only if the GL is in RGBA mode, and then only if \texttt{format} is not STENCIL\_INDEX, DEPTH\_COMPONENT, or DEPTH\_STENCIL. The R, G, B, and A values form a group of elements.

For a signed or unsigned normalized fixed-point color buffer, each element is converted to floating-point using equations 2.3 or 2.1, respectively. For an integer
or floating-point color buffer, the elements are unmodified.

**Conversion of Depth values**

This step applies only if *format* is `DEPTH_COMPONENT` or `DEPTH_STENCIL` and the depth buffer uses a fixed-point representation. An element is taken to be a fixed-point value in \([0, 1]\) with \(m\) bits, where \(m\) is the number of bits in the depth buffer (see section 2.16.1). No conversion is necessary if the depth buffer uses a floating-point representation.

**Pixel Transfer Operations**

This step is actually the sequence of steps that was described separately in section 3.7.6. After the processing described in that section is completed, groups are processed as described in the following sections.

**Conversion to \(L\)**

This step applies only to RGBA component groups. If the *format* is either `LUMINANCE` or `LUMINANCE_ALPHA`, a value \(L\) is computed as

\[
L = R + G + B
\]

where \(R\), \(G\), and \(B\) are the values of the R, G, and B components. The single computed \(L\) component replaces the R, G, and B components in the group.

**Final Conversion**

For an index, if the *type* is not `FLOAT` or `HALF_FLOAT`, final conversion consists of masking the index with the value given in table 4.8; if the *type* is `FLOAT` or `HALF_FLOAT`, then the integer index is converted to a GL float or half data value.

Read color clamping is controlled by calling `ClampColor` (see section 3.7.5) with *target* set to `CLAMP_READ_COLOR`. If `clamp` is `TRUE`, read color clamping is enabled; if `clamp` is `FALSE`, read color clamping is disabled. If `clamp` is `FIXED_ONLY`, read color clamping is enabled if the selected read color buffer has fixed-point components.

For a floating-point RGBA color, if *type* is not one of `FLOAT`, `HALF_FLOAT`, `UNSIGNED_INT_5_9_9_9_REV`, or `UNSIGNED_INT_10F_11F_11F_REV`; or if read color clamping is enabled, each component is first clamped to \([0, 1]\). Then the appropriate conversion formula from table 4.9 is applied to the component.

Table 4.8: Index masks used by ReadPixels. Floating point data are not masked.

In the special case of calling ReadPixels with type of UNSIGNED_INT_10F_11F_11F_REV and format of RGB, conversion is performed as follows: the returned data are packed into a series of uint values. The red, green, and blue components are converted to unsigned 11-bit floating-point, unsigned 11-bit floating-point, and unsigned 10-bit floating point as described in sections 2.1.3 and 2.1.4. The resulting red 11 bits, green 11 bits, and blue 10 bits are then packed as the 1st, 2nd, and 3rd components of the UNSIGNED_INT_10F_11F_11F_REV format as shown in table 3.11.

In the special case of calling ReadPixels with type of UNSIGNED_INT_5_9_9_9_REV and format RGB, the conversion is performed as follows: the returned data are packed into a series of uint values. The red, green, and blue components are converted to red_s, green_s, blue_s, and exp_shared integers as described in section 3.9.1 when internalformat is RGB9_E5. The red_s, green_s, blue_s, and exp_shared are then packed as the 1st, 2nd, 3rd, and 4th components of the UNSIGNED_INT_5_9_9_9_REV format as shown in table 3.11.

For an integer RGBA color, each component is clamped to the representable range of type.

Placement in Pixel Pack Buffer or Client Memory

If a pixel pack buffer is bound (as indicated by a non-zero value of PIXEL_PACK_BUFFER_BINDING), data is an offset into the pixel pack buffer and the pixels are packed into the buffer relative to this offset; otherwise, data is a pointer to a block client memory and the pixels are packed into the client memory relative to the pointer. If a pixel pack buffer object is bound and packing the pixel data according

Table 4.9: Reversed component conversions, used when component data are being returned to client memory. Color, normal, and depth components are converted from the internal floating-point representation \( f \) to a datum of the specified GL data type \( c \) using the specified equation. All arithmetic is done in the internal floating-point format. These conversions apply to component data returned by GL query commands and to components of pixel data returned to client memory. The equations remain the same even if the implemented ranges of the GL data types are greater than the minimum required ranges. (See table 2.2.) Equations with \( N \) as the exponent are performed for each bitfield of the packed data type, with \( N \) set to the number of bits in the bitfield.
4.3. DRAWING, READING, AND COPYING PIXELS

to the pixel pack storage state would access memory beyond the size of the pixel pack buffer’s memory size, an INVALID_OPERATION error results. If a pixel pack buffer object is bound and data is not evenly divisible by the number of basic machine units needed to store in memory the corresponding GL data type from table 3.5 for the type parameter, an INVALID_OPERATION error results.

Groups of elements are placed in memory just as they are taken from memory when transferring pixel rectangles to the GL. That is, the $i$th group of the $j$th row (corresponding to the $i$th pixel in the $j$th row) is placed in memory just where the $i$th group of the $j$th row would be taken from when transferring pixels. See Unpacking under section 3.7.4. The only difference is that the storage mode parameters whose names begin with PACK_ are used instead of those whose names begin with UNPACK_. If the format is LUMINANCE, RED, GREEN, BLUE, or ALPHA, only the corresponding single element is written. Likewise if the format is LUMINANCE_ALPHA, RG, RGB, or BGR, only the corresponding two or three elements are written. Otherwise all the elements of each group are written.

4.3.3 Copying Pixels

The command

```c
void CopyPixels(int x, int y, sizei width, sizei height,
    enum type);
```

transfers a rectangle of pixel values from one region of the read framebuffer to another in the draw framebuffer. Pixel copying is diagrammed in figure 4.3. type is a symbolic constant that must be one of COLOR, STENCIL, DEPTH, or DEPTH_STENCIL, indicating that the values to be transferred are colors, stencil values, depth values, or depth/stencil values, respectively. The first four arguments have the same interpretation as the corresponding arguments to ReadPixels.

Values are obtained from the framebuffer, converted (if appropriate), then subjected to the pixel transfer operations described in section 3.7.6, just as if ReadPixels were called with the corresponding arguments.

If the type is STENCIL or DEPTH, then it is as if the format for ReadPixels were STENCIL_INDEX or DEPTH_COMPONENT, respectively. If the type is DEPTH_STENCIL, then it is as if the format for ReadPixels were specified as described in table 4.10. If the type is COLOR, then if the GL is in RGBA mode, it is as if the format were RGBA, while if the GL is in color index mode, it is as if the format were COLOR_INDEX.

The groups of elements so obtained are then written to the framebuffer just as if DrawPixels had been given width and height, beginning with final conversion of elements. The effective format is the same as that already described.
Figure 4.3. Operation of CopyPixels. Operations in dashed boxes may be enabled or disabled. Index-to-RGBA lookup is currently never performed. RGBA and color index pixel paths are shown; depth and stencil pixel paths are not shown.
4.3. DRAWING, READING, AND COPYING PIXELS

Finally, the behavior of several GL operations is specified as if the arguments were passed to `CopyPixels`. These operations include `CopyTexImage*`, `CopyTexSubImage*`, `CopyColorTable`, `CopyColorSubTable`, and `CopyConvolutionFilter*`. An `INVALID_FRAMEBUFFER_OPERATION` error will be generated if an attempt is made to execute one of these operations, or `CopyPixels`, while the object bound to `READ_FRAMEBUFFER_BINDING` (see section 4.4) is not framebuffer complete (as defined in section 4.4.4). An `INVALID_OPERATION` error will be generated if the object bound to `READ_FRAMEBUFFER_BINDING` is framebuffer complete and the value of `SAMPLE_BUFFERS` is greater than zero.

`CopyPixels` will generate an `INVALID_FRAMEBUFFER_OPERATION` error if the object bound to `DRAW_FRAMEBUFFER_BINDING` (see section 4.4) is not framebuffer complete.

If the read buffer contains integer or unsigned integer components, an `INVALID_OPERATION` error is generated.

Blitting Pixel Rectangles

The command

```c
void BlitFramebuffer( int srcX0, int srcY0, int srcX1,
                      int srcY1, int dstX0, int dstY0, int dstX1, int dstY1,
                      bitfield mask, enum filter );
```

transfers a rectangle of pixel values from one region of the read framebuffer to another in the draw framebuffer. There are some important distinctions from `CopyPixels`, as described below.

`mask` is the bitwise OR of a number of values indicating which buffers are to be copied. The values are `COLOR_BUFFER_BIT`, `DEPTH_BUFFER_BIT`, and `STENCIL_BUFFER_BIT`, which are described in section 4.2.3. The pixels corresponding to these buffers are copied from the source rectangle bounded by the locations `(srcX0, srcY0)` and `(srcX1, srcY1)` to the destination rectangle bounded

by the locations \((dstX0, dstY0)\) and \((dstX1, dstY1)\). The lower bounds of the rectangle are inclusive, while the upper bounds are exclusive.

When the color buffer is transferred, values are taken from the read buffer of the read framebuffer and written to each of the draw buffers of the draw framebuffer, just as with \texttt{CopyPixels}.

The actual region taken from the read framebuffer is limited to the intersection of the source buffers being transferred, which may include the color buffer selected by the read buffer, the depth buffer, and/or the stencil buffer depending on \textit{mask}. The actual region written to the draw framebuffer is limited to the intersection of the destination buffers being written, which may include multiple draw buffers, the depth buffer, and/or the stencil buffer depending on \textit{mask}. Whether or not the source or destination regions are altered due to these limits, the scaling and offset applied to pixels being transferred is performed as though no such limits were present.

If the source and destination rectangle dimensions do not match, the source image is stretched to fit the destination rectangle. \textit{filter} must be \texttt{LINEAR} or \texttt{NEAREST}, and specifies the method of interpolation to be applied if the image is stretched. \texttt{LINEAR} filtering is allowed only for the color buffer; if \textit{mask} includes \texttt{DEPTH_-BUFFER_BIT} or \texttt{STENCIL_BUFFER_BIT}, and \textit{filter} is not \texttt{NEAREST}, no copy is performed and an \texttt{INVALID_OPERATION} error is generated. If the source and destination dimensions are identical, no filtering is applied. If either the source or destination rectangle specifies a negative width or height \((X1 < X0 \text{ or } Y1 < Y0)\), the image is reversed in the corresponding direction. If both the source and destination rectangles specify a negative width or height for the same direction, no reversal is performed. If a linear filter is selected and the rules of \texttt{LINEAR} sampling would require sampling outside the bounds of a source buffer, it is as though \texttt{CLAMP_TO_EDGE} texture sampling were being performed. If a linear filter is selected and sampling would be required outside the bounds of the specified source region, but within the bounds of a source buffer, the implementation may choose to clamp while sampling or not.

If the source and destination buffers are identical, and the source and destination rectangles overlap, the result of the blit operation is undefined.

Blit operations bypass the fragment pipeline. The only fragment operations which affect a blit are the pixel ownership test and the scissor test.

If the read framebuffer is layered (see section 4.4.7), pixel values are read from layer zero. If the draw framebuffer is layered, pixel values are written to layer zero. If both read and draw framebuffers are layered, the blit operation is still performed only on layer zero.

If a buffer is specified in \textit{mask} and does not exist in both the read and draw framebuffers, the corresponding bit is silently ignored.
4.3. DRAWING, READING, AND COPYING PIXELS

If the color formats of the read and draw buffers do not match, and \textit{mask} includes \texttt{COLOR\_BUFFER\_BIT}, pixel groups are converted to match the destination format as in \texttt{CopyPixels}. However, no pixel transfer operations are applied, and colors are clamped only if all draw color buffers have fixed-point components, as if \texttt{CLAMP\_FRAGMENT\_COLOR} were set to \texttt{FIXED\_ONLY}. Format conversion is not supported for all data types, and an \texttt{INVALID\_OPERATION} error is generated under any of the following conditions:

- The read buffer contains fixed-point or floating-point values and any draw buffer contains neither fixed-point nor floating-point values.
- The read buffer contains unsigned integer values and any draw buffer does not contain unsigned integer values.
- The read buffer contains signed integer values and any draw buffer does not contain signed integer values.

Calling \texttt{BlitFramebuffer} will result in an \texttt{INVALID\_FRAMEBUFFER\_OPERATION} error if the objects bound to \texttt{DRAW\_FRAMEBUFFER\_BINDING} and \texttt{READ\_FRAMEBUFFER\_BINDING} are not framebuffer complete (section 4.4.4).

Calling \texttt{BlitFramebuffer} will result in an \texttt{INVALID\_OPERATION} error if \textit{mask} includes \texttt{DEPTH\_BUFFER\_BIT} or \texttt{STENCIL\_BUFFER\_BIT}, and the source and destination depth and stencil buffer formats do not match.

Calling \texttt{BlitFramebuffer} will result in an \texttt{INVALID\_OPERATION} error if \textit{filter} is \texttt{LINEAR} and read buffer contains integer data.

If \texttt{SAMPLE\_BUFFERS} for the read framebuffer is greater than zero and \texttt{SAMPLE\_BUFFERS} for the draw framebuffer is zero, the samples corresponding to each pixel location in the source are converted to a single sample before being written to the destination.

If \texttt{SAMPLE\_BUFFERS} for the read framebuffer is zero and \texttt{SAMPLE\_BUFFERS} for the draw framebuffer is greater than zero, the value of the source sample is replicated in each of the destination samples.

If \texttt{SAMPLE\_BUFFERS} for either the read framebuffer or draw framebuffer is greater than zero, no copy is performed and an \texttt{INVALID\_OPERATION} error is generated if the dimensions of the source and destination rectangles provided to \texttt{BlitFramebuffer} are not identical, if the formats of the read and draw framebuffers are not identical, or if the values of \texttt{SAMPLES} for the read and draw buffers are not identical.

If \texttt{SAMPLE\_BUFFERS} for both the read and draw framebuffers are greater than zero, and the values of \texttt{SAMPLES} for the read and draw framebuffers are identical, the samples are copied without modification from the read framebuffer to the draw...
4.4. FRAMEBUFFER OBJECTS

framebuffer. Otherwise, no copy is performed and an INVALID_OPERATION error is generated. Note that the samples in the draw buffer are not guaranteed to be at the same sample location as the read buffer, so rendering using this newly created buffer can potentially have geometry cracks or incorrect antialiasing. This may occur if the sizes of the framebuffers do not match, if the formats differ, or if the source and destination rectangles are not defined with the same \((X_0, Y_0)\) and \((X_1, Y_1)\) bounds.

4.3.4 Pixel Draw/Read State

The state required for pixel operations consists of the parameters that are set with PixelStore, PixelTransfer, and PixelMap. This state has been summarized in tables 3.1, 3.2, and 3.3. Additional state includes the current raster position (section 2.24), an integer indicating the current setting of ReadBuffer, and a three-valued integer controlling clamping during final conversion. For the default framebuffer, in the initial state the read buffer is BACK if there is a back buffer; FRONT if there is no back buffer; and NONE if no default framebuffer is associated with the context. The initial value of read color clamping is FIXED_ONLY. State set with PixelStore is GL client state.

4.4 Framebuffer Objects

As described in chapter 1 and section 2.1, the GL renders into (and reads values from) a framebuffer. GL defines two classes of framebuffers: window system-provided and application-created.

Initially, the GL uses the default framebuffer. The storage, dimensions, allocation, and format of the images attached to this framebuffer are managed entirely by the window system. Consequently, the state of the default framebuffer, including its images, can not be changed by the GL, nor can the default framebuffer be deleted by the GL.

The routines described in the following sections, however, can be used to create, destroy, and modify the state and attachments of framebuffer objects.

Framebuffer objects encapsulate the state of a framebuffer in a similar manner to the way texture objects encapsulate the state of a texture. In particular, a framebuffer object encapsulates state necessary to describe a collection of color, depth, and stencil logical buffers (other types of buffers are not allowed). For each logical buffer, a framebuffer-attachable image can be attached to the framebuffer to store the rendered output for that logical buffer. Examples of framebuffer-attachable images include texture images and renderbuffer images. Renderbuffers are described
further in section 4.4.2

By allowing the images of a renderbuffer to be attached to a framebuffer, the
GL provides a mechanism to support off-screen rendering. Further, by allowing the
images of a texture to be attached to a framebuffer, the GL provides a mechanism
to support render to texture.

4.4.1 Binding and Managing Framebuffer Objects

The default framebuffer for rendering and readback operations is provided by the
window system. In addition, named framebuffer objects can be created and operated
upon. The namespace for framebuffer objects is the unsigned integers, with
zero reserved by the GL for the default framebuffer.

A framebuffer object is created by binding a name returned by GenFrame-
buffers (see below) to DRAW_FRAMEBUFFER or READ_FRAMEBUFFER. The bind-
ing is effected by calling

    void BindFramebuffer( enum target, uint framebuffer );

with target set to the desired framebuffer target and framebuffer set to the frame-
buffer object name. The resulting framebuffer object is a new state vector, com-
prising all the state values listed in table 6.30, as well as one set of the state values
listed in table 6.31 for each attachment point of the framebuffer, set to the same
initial values. There are MAX_COLOR_ATTACHMENTS color attachment points, plus
one each for the depth and stencil attachment points.

BindFramebuffer may also be used to bind an existing framebuffer object
to DRAW_FRAMEBUFFER and/or READ_FRAMEBUFFER. If the bind is successful no
change is made to the state of the bound framebuffer object, and any previous
binding to target is broken.

BindFramebuffer fails and an INVALID_OPERATION error is generated if
framebuffer is not zero or a name returned from a previous call to GenFrame-
buffers, or if such a name has since been deleted with DeleteFramebuffers.

If a framebuffer object is bound to DRAW_FRAMEBUFFER or READ_FRAMEBUFFER, it becomes the target for rendering or readback operations, respec-
tively, until it is deleted or another framebuffer is bound to the corresponding bind
point. Calling BindFramebuffer with target set to FRAMEBUFFER binds frame-
buffer to both the draw and read targets.

While a framebuffer object is bound, GL operations on the target to which it
is bound affect the images attached to the bound framebuffer object, and queries
of the target to which it is bound return state from the bound object. Queries of
the values specified in tables 6.60 and 6.33 are derived from the framebuffer object
bound to DRAW_FRAMEBUFFER.
4.4. FRAMEBUFFER OBJECTS

The initial state of `DRAW_FRAMEBUFFER` and `READ_FRAMEBUFFER` refers to the default framebuffer. In order that access to the default framebuffer is not lost, it is treated as a framebuffer object with the name of zero. The default framebuffer is therefore rendered to and read from while zero is bound to the corresponding targets. On some implementations, the properties of the default framebuffer can change over time (e.g., in response to window system events such as attaching the context to a new window system drawable.)

Framebuffer objects (those with a non-zero name) differ from the default framebuffer in a few important ways. First and foremost, unlike the default framebuffer, framebuffer objects have modifiable attachment points for each logical buffer in the framebuffer. Framebuffer-attachable images can be attached to and detached from these attachment points, which are described further in section 4.4.2. Also, the size and format of the images attached to framebuffer objects are controlled entirely within the GL interface, and are not affected by window system events, such as pixel format selection, window resizes, and display mode changes.

Additionally, when rendering to or reading from an application created-framebuffer object,

- The pixel ownership test always succeeds. In other words, framebuffer objects own all of their pixels.
- There are no visible color buffer bitplanes. This means there is no color buffer corresponding to the back, front, left, or right color bitplanes.
- The only color buffer bitplanes are the ones defined by the framebuffer attachment points named `COLOR_ATTACHMENT0` through `COLOR_ATTACHMENTn`.
- The only depth buffer bitplanes are the ones defined by the framebuffer attachment point `DEPTH_ATTACHMENT`.
- The only stencil buffer bitplanes are the ones defined by the framebuffer attachment point `STENCIL_ATTACHMENT`.
- There are no accumulation buffer bitplanes, so the value of the implementation-dependent state variables `ACCUM_RED_BITS`, `ACCUM_GREEN_BITS`, `ACCUM_BLUE_BITS`, and `ACCUM_ALPHA_BITS` are all zero.
- There are no `AUX` buffer bitplanes, so the value of the implementation-dependent state variable `AUX_BUFFERS` is zero.
- If the attachment sizes are not all identical, rendering will be limited to the largest area that can fit in all of the attachments (an intersection of rectangles
having a lower left of \((0,0)\) and an upper right of \((\text{width, height})\) for each attachment).

- If the number of layers of each attachment are not all identical, rendering will be limited to the smallest number of layers of any attachment.
- If the attachment sizes are not all identical, the values of pixels outside the common intersection area after rendering are undefined.

Framebuffer objects are deleted by calling

```c
void DeleteFramebuffers(sizei n, uint *framebuffers);
```

`framebuffers` contains `n` names of framebuffer objects to be deleted. After a framebuffer object is deleted, it has no attachments, and its name is again unused. If a framebuffer that is currently bound to one or more of the targets `DRAW_FRAMEBUFFER` or `READ_FRAMEBUFFER` is deleted, it is as though `BindFramebuffer` had been executed with the corresponding `target` and `framebuffer` zero. Unused names in `framebuffers` are silently ignored, as is the value zero.

The command

```c
void GenFramebuffers(sizei n, uint *ids);
```

returns `n` previously unused framebuffer object names in `ids`. These names are marked as used, for the purposes of `GenFramebuffers` only, but they acquire state and type only when they are first bound.

The names bound to the draw and read framebuffer bindings can be queried by calling `GetIntegerv` with the symbolic constants `DRAW_FRAMEBUFFER_BINDING` and `READ_FRAMEBUFFER_BINDING`, respectively. `FRAMEBUFFER_BINDING` is equivalent to `DRAW_FRAMEBUFFER_BINDING`.

### 4.4.2 Attaching Images to Framebuffer Objects

Framebuffer-attachable images may be attached to, and detached from, framebuffer objects. In contrast, the image attachments of the default framebuffer may not be changed by the GL.

A single framebuffer-attachable image may be attached to multiple framebuffer objects, potentially avoiding some data copies, and possibly decreasing memory consumption.

For each logical buffer, a framebuffer object stores a set of state which defines the logical buffer’s attachment point. The attachment point state contains enough
information to identify the single image attached to the attachment point, or to indicate that no image is attached. The per-logical buffer attachment point state is listed in table 6.31.

There are several types of framebuffer-attachable images:

- The image of a renderbuffer object, which is always two-dimensional.
- A single level of a one-dimensional texture, which is treated as a two-dimensional image with a height of one.
- A single level of a two-dimensional or rectangle texture.
- A single face of a cube map texture level, which is treated as a two-dimensional image.
- A single layer of a one-or two-dimensional array texture or three-dimensional texture, which is treated as a two-dimensional image.

Additionally, an entire level of a three-dimensional texture, cube map texture, or one-or two-dimensional array texture can be attached to an attachment point. Such attachments are treated as an array of two-dimensional images, arranged in layers, and the corresponding attachment point is considered to be layered (also see section 4.4.7).

### Renderbuffer Objects

A renderbuffer is a data storage object containing a single image of a renderable internal format. GL provides the methods described below to allocate and delete a renderbuffer’s image, and to attach a renderbuffer’s image to a framebuffer object.

The name space for renderbuffer objects is the unsigned integers, with zero reserved for the GL. A renderbuffer object is created by binding a name returned by GenRenderbuffers (see below) to RENDERBUFFER. The binding is effected by calling

```c
void BindRenderbuffer( enum target, uint renderbuffer );
```

with `target` set to RENDERBUFFER and `renderbuffer` set to the renderbuffer object name. If `renderbuffer` is not zero, then the resulting renderbuffer object is a new state vector, initialized with a zero-sized memory buffer, and comprising the state values listed in table 6.33. Any previous binding to `target` is broken.

`BindRenderbuffer` may also be used to bind an existing renderbuffer object. If the bind is successful, no change is made to the state of the newly bound renderbuffer object, and any previous binding to `target` is broken.
While a renderbuffer object is bound, GL operations on the target to which it is bound affect the bound renderbuffer object, and queries of the target to which a renderbuffer object is bound return state from the bound object.

The name zero is reserved. A renderbuffer object cannot be created with the name zero. If renderbuffer is zero, then any previous binding to target is broken and the target binding is restored to the initial state.

In the initial state, the reserved name zero is bound to RENDERBUFFER. There is no renderbuffer object corresponding to the name zero, so client attempts to modify or query renderbuffer state for the target RENDERBUFFER while zero is bound will generate GL errors, as described in section 6.1.3.

The current RENDERBUFFER binding can be determined by calling GetIntegerv with the symbolic constant RENDERBUFFER_BINDING.

BindRenderbuffer fails and an INVALID_OPERATION error is generated if renderbuffer is not zero or a name returned from a previous call to GenRenderbuffers, or if such a name has since been deleted with DeleteRenderbuffers.

Renderbuffer objects are deleted by calling

```c
void DeleteRenderbuffers( sizei n, const uint *renderbuffers );
```

where renderbuffers contains n names of renderbuffer objects to be deleted. After a renderbuffer object is deleted, it has no contents, and its name is again unused. If a renderbuffer that is currently bound to RENDERBUFFER is deleted, it is as though BindRenderbuffer had been executed with the target RENDERBUFFER and name of zero. Additionally, special care must be taken when deleting a renderbuffer if the image of the renderbuffer is attached to a framebuffer object (see section 4.4.2). Unused names in renderbuffers are silently ignored, as is the value zero.

The command

```c
void GenRenderbuffers( sizei n, uint *renderbuffers );
```

returns n previously unused renderbuffer object names in renderbuffers. These names are marked as used, for the purposes of GenRenderbuffers only, but they acquire renderbuffer state only when they are first bound.

The command

```c
void RenderbufferStorageMultisample( enum target, 
   sizei samples, enum internalformat, sizei width, 
   sizei height );
```
4.4. FRAMEBUFFER OBJECTS

<table>

</tr>
</tbody>
</table>

Table 4.11: Correspondence of sized internal formats to base internal formats for formats that can be used only with renderbuffers.

establishes the data storage, format, dimensions, and number of samples of a renderbuffer object’s image. `target` must be RENDERBUFFER. `internalformat` must be color-renderable, depth-renderable, or stencil-renderable (as defined in section 4.4.4). `width` and `height` are the dimensions in pixels of the renderbuffer. If either `width` or `height` is greater than the value of `MAX_RENDERBUFFER_SIZE`, or if `samples` is greater than the value of `MAX_SAMPLES`, then the error `INVALID_VALUE` is generated. If `internalformat` is a signed or unsigned integer format and `samples` is greater than the value of `MAX_INTEGER_SAMPLES`, then the error `INVALID_OPERATION` is generated (see “Required Renderbuffer Formats” below). If the GL is unable to create a data store of the requested size, the error `OUT_OF_MEMORY` is generated.

Upon success, `RenderbufferStorageMultisample` deletes any existing data store for the renderbuffer image and the contents of the data store after calling `RenderbufferStorageMultisample` are undefined. `RENDERBUFFER_WIDTH` is set to `width`, `RENDERBUFFER_HEIGHT` is set to `height`, and `RENDERBUFFER_INTERNAL_FORMAT` is set to `internalformat`.

If `samples` is zero, then `RENDERBUFFER_SAMPLES` is set to zero. Otherwise `samples` represents a request for a desired minimum number of samples. Since different implementations may support different sample counts for multisampled rendering, the actual number of samples allocated for the renderbuffer image is implementation-dependent. However, the resulting value for `RENDERBUFFER_SAMPLES` is guaranteed to be greater than or equal to `samples` and no more than the next larger sample count supported by the implementation.

A GL implementation may vary its allocation of internal component resolution based on any `RenderbufferStorage` parameter (except target), but the allocation and chosen internal format must not be a function of any other state and cannot be changed once they are established.

The command
4.4. FRAMEBUFFER OBJECTS

```c
void RenderbufferStorage( enum target, enum internalformat,
                         sizei width, sizei height );
```

is equivalent to calling `RenderbufferStorageMultisample` with `samples` equal to zero.

**Required Renderbuffer Formats**

Implementations are required to support the same internal formats for renderbuffers as the required formats for textures enumerated in section 3.9.1, with the exception of the color formats labelled “texture-only”. Requesting one of these internal formats for a renderbuffer will allocate at least the internal component sizes and exactly the component types shown for that format in tables 3.17-3.19.

Implementations must support creation of renderbuffers in these required formats with up to the value of `MAX_SAMPLES` multisamples, with the exception that the signed and unsigned integer formats are required only to support creation of renderbuffers with up to the value of `MAX_INTEGER_SAMPLES` multisamples, which must be at least one.

**Attaching Renderbuffer Images to a Framebuffer**

A renderbuffer can be attached as one of the logical buffers of the currently bound framebuffer object by calling

```c
void FramebufferRenderbuffer( enum target,
                              enum attachment, enum renderbuffertarget,
                              uint renderbuffer );
```

target must be DRAW_FRAMEBUFFER, READ_FRAMEBUFFER, or FRAMEBUFFER. FRAMEBUFFER is equivalent to DRAW_FRAMEBUFFER. An INVALID_OPERATION error is generated if the value of the corresponding binding is zero. attachment should be set to one of the attachment points of the framebuffer listed in table 4.12.

renderbuffertarget must be RENDERBUFFER and renderbuffer should be set to the name of the renderbuffer object to be attached to the framebuffer. renderbuffer must be either zero or the name of an existing renderbuffer object of type renderbuffertarget, otherwise an INVALID_OPERATION error is generated. If renderbuffer is zero, then the value of renderbuffertarget is ignored.

If renderbuffer is not zero and if `FramebufferRenderbuffer` is successful, then the renderbuffer named renderbuffer will be used as the logical buffer identified by attachment of the framebuffer currently bound to target. The value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE for the specified attachment point is
set to `RENDERBUFFER` and the value of `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME` is set to `renderbuffer`. All other state values of the attachment point specified by `attachment` are set to their default values listed in table 6.31. No change is made to the state of the renderbuffer object and any previous attachment to the attachment logical buffer of the framebuffer object bound to framebuffer `target` is broken. If the attachment is not successful, then no change is made to the state of either the renderbuffer object or the framebuffer object.

Calling `FramebufferRenderbuffer` with the `renderbuffer` name zero will detach the image, if any, identified by `attachment`, in the framebuffer currently bound to `target`. All state values of the attachment point specified by `attachment` in the object bound to `target` are set to their default values listed in table 6.31.

Setting `attachment` to the value `DEPTH_STENCIL_ATTACHMENT` is a special case causing both the depth and stencil attachments of the framebuffer object to be set to `renderbuffer`, which should have base internal format `DEPTH_STENCIL`.

If a renderbuffer object is deleted while its image is attached to one or more attachment points in the currently bound framebuffer, then it is as if `FramebufferRenderbuffer` had been called, with a `renderbuffer` of 0, for each attachment point to which this image was attached in the currently bound framebuffer. In other words, this renderbuffer image is first detached from all attachment points in the currently bound framebuffer. Note that the renderbuffer image is specifically not detached from any non-bound framebuffers. Detaching the image from any non-bound framebuffers is the responsibility of the application.

Table 4.12: Framebuffer attachment points. `i` in `COLOR_ATTACHMENTi` may range from zero to the value of `MAX_COLOR_ATTACHMENTS` - 1.

**Attaching Texture Images to a Framebuffer**

GL supports copying the rendered contents of the framebuffer into the images of a texture object through the use of the routines `CopyTexImage*` and `CopyTexSubImage*`. Additionally, GL supports rendering directly into the images of a texture object.
To render directly into a texture image, a specified level of a texture object can be attached as one of the logical buffers of the currently bound framebuffer object by calling:

```c
void FramebufferTexture( enum target, enum attachment,
                      uint texture, int level);
```

`target` must be `DRAW_FRAMEBUFFER`, `READ_FRAMEBUFFER`, or `FRAMEBUFFER`. `FRAMEBUFFER` is equivalent to `DRAW_FRAMEBUFFER`. An `INVALID_OPERATION` error is generated if the value of the corresponding binding is zero. `attachment` must be one of the attachment points of the framebuffer listed in table 4.12.

If `texture` is non-zero, the specified mipmap `level` of the texture object named `texture` is attached to the framebuffer attachment point named by `attachment`. An `INVALID_VALUE` error is generated if `texture` is not the name of a texture object, or if `level` is not a supported texture level number for textures of the type corresponding to `target`. An `INVALID_OPERATION` error is generated if `texture` is the name of a buffer texture.

If `texture` is the name of a three-dimensional texture, cube map texture, one- or two-dimensional array texture, or two-dimensional multisample array texture, the texture level attached to the framebuffer attachment point is an array of images, and the framebuffer attachment is considered layered.

Additionally, a specified image from a texture object can be attached as one of the logical buffers of the currently bound framebuffer object by calling one of the following routines, depending on the type of the texture:

```c
void FramebufferTexture1D( enum target, enum attachment,
                      enum textarget, uint texture, int level);
void FramebufferTexture2D( enum target, enum attachment,
                      enum textarget, uint texture, int level);
void FramebufferTexture3D( enum target, enum attachment,
                      enum textarget, uint texture, int level, int layer);
```

In all three routines, `target` must be `DRAW_FRAMEBUFFER`, `READ_FRAMEBUFFER`, or `FRAMEBUFFER`. `FRAMEBUFFER` is equivalent to `DRAW_FRAMEBUFFER`. An `INVALID_OPERATION` error is generated if the value of the corresponding binding is zero. `attachment` must be one of the attachment points of the framebuffer listed in table 4.12.

If `texture` is not zero, then `texture` must either name an existing texture object with an target of `textarget`, or `texture` must name an existing cube map.
texture and textarget must be one of TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, or TEXTURE_CUBE_MAP_NEGATIVE_Z. Otherwise, an INVALID_OPERATION error is generated.

level specifies the mipmap level of the texture image to be attached to the framebuffer.

If textarget is TEXTURE_RECTANGLE, TEXTURE_2D_MULTISAMPLE, or TEXTURE_2D_MULTISAMPLE_ARRAY, then level must be zero. If textarget is TEXTURE_3D, then level must be greater than or equal to zero and less than or equal to log_2 of the value of MAX_3D_TEXTURE_SIZE. If textarget is one of TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, or TEXTURE_CUBE_MAP_NEGATIVE_Z, then level must be greater than or equal to zero and less than or equal to log_2 of the value of MAX_CUBE_MAP_TEXTURE_SIZE. For all other values of textarget, level must be greater than or equal to zero and no larger than log_2 of the value of MAX_TEXTURE_SIZE. Otherwise, an INVALID_VALUE error is generated.

layer specifies the layer of a 2-dimensional image within a 3-dimensional texture. An INVALID_VALUE error is generated if layer is larger than the value of MAX_3D_TEXTURE_SIZE-1.

For FramebufferTexture1D, if texture is not zero, then textarget must be TEXTURE_1D.

For FramebufferTexture2D, if texture is not zero, then textarget must be one of TEXTURE_2D, TEXTURE_RECTANGLE, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Z, or TEXTURE_2D_MULTISAMPLE.

For FramebufferTexture3D, if texture is not zero, then textarget must be TEXTURE_3D.

The command

```c
void FramebufferTextureLayer( enum target,
      enum attachment, uint texture, int level, int layer );
```

operates identically to FramebufferTexture3D, except that it attaches a single layer of a three-dimensional, one-or two-dimensional array texture, or two-dimensional multisample array texture. layer is an integer indicating the layer number, and is treated identically to the layer parameter in FramebufferTexture3D.
The error `INVALID_VALUE` is generated if `texture` is non-zero and `layer` is negative. The error `INVALID_OPERATION` is generated if `texture` is non-zero and is not the name of a three dimensional, two-dimensional multisample array, or one-or two-dimensional array texture. Unlike `FramebufferTexture3D`, no `textarget` parameter is accepted.

If `texture` is non-zero and the command does not result in an error, the framebuffer attachment state corresponding to `attachment` is updated as in the other `FramebufferTexture` commands, except that the value of `FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER` is set to `layer`.

**Effects of Attaching a Texture Image**

The remaining comments in this section apply to all forms of `FramebufferTexture*`.

If `texture` is zero, any image or array of images attached to the attachment point named by `attachment` is detached. Any additional parameters (level, `textarget`, and/or `layer`) are ignored when `texture` is zero. All state values of the attachment point specified by `attachment` are set to their default values listed in table 6.31.

If `texture` is not zero, and if `FramebufferTexture*` is successful, then the specified texture image will be used as the logical buffer identified by `attachment` of the framebuffer currently bound to `target`. State values of the specified attachment point are set as follows:

- The value of `FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE` is set to `TEXTURE`.
- The value of `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME` is set to `texture`.
- The value of `FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL` is set to `level`.
- If `FramebufferTexture2D` is called and `texture` is a cube map texture, then the value of `FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE` is set to `textarget`; otherwise it is set to `TEXTURE_CUBE_MAP_POSITIVE_X`.
- If `FramebufferTextureLayer` or `FramebufferTexture3D` is called, then the value of `FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER` is set to `layer`; otherwise it is set to zero.
- If `FramebufferTexture` is called and `texture` is the name of a three-dimensional, cube map, two-dimensional multisample array, or one-or two-dimensional array texture, the value of `FRAMEBUFFER_ATTACHMENT_LAYERED` is set to `TRUE`; otherwise it is set to `FALSE`.
All other state values of the attachment point specified by attachment are set to their default values listed in table 6.31. No change is made to the state of the texture object, and any previous attachment to the attachment logical buffer of the framebuffer object bound to framebuffer target is broken. If the attachment is not successful, then no change is made to the state of either the texture object or the framebuffer object.

Setting attachment to the value DEPTH_STENCIL_ATTACHMENT is a special case causing both the depth and stencil attachments of the framebuffer object to be set to texture. texture must have base internal format DEPTH_STENCIL, or the depth and stencil framebuffer attachments will be incomplete (see section 4.4.4).

If a texture object is deleted while its image is attached to one or more attachment points in the currently bound framebuffer, then it is as if FramebufferTexture* had been called, with a texture of zero, for each attachment point to which this image was attached in the currently bound framebuffer. In other words, this texture image is first detached from all attachment points in the currently bound framebuffer. Note that the texture image is specifically not detached from any other framebuffer objects. Detaching the texture image from any other framebuffer objects is the responsibility of the application.

4.4.3 Feedback Loops Between Textures and the Framebuffer

A feedback loop may exist when a texture object is used as both the source and destination of a GL operation. When a feedback loop exists, undefined behavior results. This section describes rendering feedback loops (see section 3.9.9) and texture copying feedback loops (see section 3.9.2) in more detail.

Rendering Feedback Loops

The mechanisms for attaching textures to a framebuffer object do not prevent a one- or two-dimensional texture level, a face of a cube map texture level, or a layer of a two-dimensional array or three-dimensional texture from being attached to the draw framebuffer while the same texture is bound to a texture unit. While this conditions holds, texturing operations accessing that image will produce undefined results, as described at the end of section 3.9.9. Conditions resulting in such undefined behavior are defined in more detail below. Such undefined texturing operations are likely to leave the final results of the shader or fixed-function fragment processing operations undefined, and should be avoided.

Special precautions need to be taken to avoid attaching a texture image to the currently bound framebuffer while the texture object is currently bound and enabled for texturing. Doing so could lead to the creation of a rendering feedback
loop between the writing of pixels by GL rendering operations and the simultaneous reading of those same pixels when used as texels in the currently bound texture. In this scenario, the framebuffer will be considered framebuffer complete (see section 4.4.4), but the values of fragments rendered while in this state will be undefined. The values of texture samples may be undefined as well, as described under “Rendering Feedback Loops” in section 3.9.9.

Specifically, the values of rendered fragments are undefined if all of the following conditions are true:

- an image from texture object $T$ is attached to the currently bound draw framebuffer at attachment point $A$,
- the texture object $T$ is currently bound to a texture unit $U$, and
- the current fixed-function texture state or programmable vertex and/or fragment processing state makes it possible (see below) to sample from the texture object $T$ bound to texture unit $U$.

while either of the following conditions are true:

- the value of \textsc{texture\_min\_filter} for texture object $T$ is \textsc{nearest} or \textsc{linear}, and the value of \textsc{framebuffer\_attachment\_texture\_level} for attachment point $A$ is equal to the value of \textsc{texture\_base\_level} for the texture object $T$.
- the value of \textsc{texture\_min\_filter} for texture object $T$ is one of \textsc{nearest\_mipmap\_nearest}, \textsc{nearest\_mipmap\_linear}, \textsc{linear\_mipmap\_nearest}, or \textsc{linear\_mipmap\_linear}, and the value of \textsc{framebuffer\_attachment\_texture\_level} for attachment point $A$ is within the range specified by the current values of \textsc{texture\_base\_level} to \textsc{q}, inclusive, for the texture object $T$. ($q$ is defined in the Mipmapping discussion of section 3.9.9).

For the purpose of this discussion, it is possible to sample from the texture object $T$ bound to texture unit $U$ if any of the following are true:

- Programmable fragment processing is disabled and the target of texture object $T$ is enabled according to the texture target precedence rules of section 3.9.19
- The active fragment or vertex shader contains any instructions that might sample from the texture object $T$ bound to $U$, even if those instructions might only be executed conditionally.
Note that if `TEXTURE_BASE_LEVEL` and `TEXTURE_MAX_LEVEL` exclude any levels containing image(s) attached to the currently bound framebuffer, then the above conditions will not be met (i.e., the above rule will not cause the values of rendered fragments to be undefined.)

**Texture Copying Feedback Loops**

Similarly to rendering feedback loops, it is possible for a texture image to be attached to the read framebuffer while the same texture image is the destination of a `CopyTexImage*` operation, as described under “Texture Copying Feedback Loops” in section 3.9.2. While this condition holds, a texture copying feedback loop between the writing of texels by the copying operation and the reading of those same texels when used as pixels in the read framebuffer may exist. In this scenario, the values of texels written by the copying operation will be undefined (in the same fashion that overlapping copies via `BlitFramebuffer` are undefined).

Specifically, the values of copied texels are undefined if all of the following conditions are true:

- an image from texture object $T$ is attached to the currently bound read framebuffer at attachment point $A$
- the selected read buffer is attachment point $A$
- $T$ is bound to the texture target of a `CopyTexImage*` operation
- the `level` argument of the copying operation selects the same image that is attached to $A$

### 4.4.4 Framebuffer Completeness

A framebuffer must be framebuffer complete to effectively be used as the draw or read framebuffer of the GL.

The default framebuffer is always complete if it exists; however, if no default framebuffer exists (no window system-provided drawable is associated with the GL context), it is deemed to be incomplete.

A framebuffer object is said to be framebuffer complete if all of its attached images, and all framebuffer parameters required to utilize the framebuffer for rendering and reading, are consistently defined and meet the requirements defined below. The rules of framebuffer completeness are dependent on the properties of the attached images, and on certain implementation-dependent restrictions.
4.4. FRAMEBUFFER OBJECTS

The internal formats of the attached images can affect the completeness of the framebuffer, so it is useful to first define the relationship between the internal format of an image and the attachment points to which it can be attached.

- The following base internal formats from table 3.16 are color-renderable: ALPHA, RED, RG, RGB, and RGBA. The sized internal formats from table 3.17 that have a color-renderable base internal format are also color-renderable. No other formats, including compressed internal formats, are color-renderable.

- An internal format is depth-renderable if it is DEPTH_COMPONENT or one of the formats from table 3.19 whose base internal format is DEPTH_COMPONENT or DEPTH_STENCIL. No other formats are depth-renderable.

- An internal format is stencil-renderable if it is STENCIL_INDEX or DEPTH_STENCIL, if it is one of the STENCIL_INDEX formats from table 4.11, or if it is one of the formats from table 3.19 whose base internal format is DEPTH_STENCIL. No other formats are stencil-renderable.

Framebuffer Attachment Completeness

If the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE for the framebuffer attachment point attachment is not NONE, then it is said that a framebuffer-attachable image, named image, is attached to the framebuffer at the attachment point. image is identified by the state in attachment as described in section 4.4.2.

The framebuffer attachment point attachment is said to be framebuffer attachment complete if the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE for attachment is NONE (i.e., no image is attached), or if all of the following conditions are true:

- image is a component of an existing object with the name specified by the value of FRAMEBUFFER_ATTACHMENT_OBJECT_NAME, and of the type specified by the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE.

- The width and height of image are non-zero.

- If the value of FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE is TEXTURE and the value of FRAMEBUFFER_ATTACHMENT_OBJECT_NAME names a three-dimensional texture, then the value of FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER must be smaller than the depth of the texture.
4.4. FRAMEBUFFER OBJECTS

- If the value of `FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE` is `TEXTURE` and the value of `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME` names a one-or two-dimensional array texture, then the value of `FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER` must be smaller than the number of layers in the texture.

- If `attachment` is `COLOR_ATTACHMENTi`, then `image` must have a color-renderable internal format.

- If `attachment` is `DEPTH_ATTACHMENT`, then `image` must have a depth-renderable internal format.

- If `attachment` is `STENCIL_ATTACHMENT`, then `image` must have a stencil-renderable internal format.

Whole Framebuffer Completeness

Each rule below is followed by an error token enclosed in `{ brackets }`. The meaning of these errors is explained below and under “Effects of Framebuffer Completeness on Framebuffer Operations” later in section 4.4.4.

The framebuffer object `target` is said to be `framebuffer complete` if all the following conditions are true:

- `target` is the default framebuffer, and the default framebuffer exists.

  `{ FRAMEBUFFER_UNDEFINED }`

- All framebuffer attachment points are `framebuffer attachment complete`.

  `{ FRAMEBUFFER_INCOMPLETE_ATTACHMENT }`

- There is at least one image attached to the framebuffer.

  `{ FRAMEBUFFER_INCOMPLETE_MISSING_ATTACHMENT }`

- The value of `FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE` must not be `NONE` for any color attachment point(s) named by `DRAW_BUFFERi`.

  `{ FRAMEBUFFER_INCOMPLETE_DRAW_BUFFER }`

- If `READ_BUFFER` is not `NONE`, then the value of `FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE` must not be `NONE` for the color attachment point named by `READ_BUFFER`.

  `{ FRAMEBUFFER_INCOMPLETE_READBUFFER }`
4.4. **FRAMEBUFFER OBJECTS**

{ FRAMEBUFFER_INCOMPLETE_READ_BUFFER }

- The combination of internal formats of the attached images does not violate an implementation-dependent set of restrictions.

{ FRAMEBUFFER_UNSUPPORTED }

- The value of RENDERBUFFER_SAMPLES is the same for all attached renderbuffers; the value of TEXTURE_SAMPLES is the same for all attached textures; and, if the attached images are a mix of renderbuffers and textures, the value of RENDERBUFFER_SAMPLES matches the value of TEXTURE_SAMPLES.

{ FRAMEBUFFER_INCOMPLETE_MULTISAMPLE }

- The value of TEXTURE_FIXED_SAMPLE_LOCATIONS is the same for all attached textures; and, if the attached images are a mix of renderbuffers and textures, the value of TEXTURE_FIXED_SAMPLE_LOCATIONS must be TRUE for all attached textures.

{ FRAMEBUFFER_INCOMPLETE_MULTISAMPLE }

- If any framebuffer attachment is layered, all populated attachments must be layered. Additionally, all populated color attachments must be from textures of the same target.

{ FRAMEBUFFER_INCOMPLETE_LAYER_TARGETS }

The token in brackets after each clause of the framebuffer completeness rules specifies the return value of CheckFramebufferStatus (see below) that is generated when that clause is violated. If more than one clause is violated, it is implementation-dependent which value will be returned by CheckFramebufferStatus.

Performing any of the following actions may change whether the framebuffer is considered complete or incomplete:

- Binding to a different framebuffer with **BindFramebuffer**.
- Attaching an image to the framebuffer with **FramebufferTexture** or **FramebufferRenderbuffer**.
• Detaching an image from the framebuffer with \texttt{FramebufferTexture} or \texttt{FramebufferRenderbuffer}.

• Changing the internal format of a texture image that is attached to the framebuffer by calling \texttt{CopyTexImage} or \texttt{CompressedTexImage}.

• Changing the internal format of a renderbuffer that is attached to the framebuffer by calling \texttt{RenderbufferStorage}.

• Deleting, with \texttt{DeleteTextures} or \texttt{DeleteRenderbuffers}, an object containing an image that is attached to a framebuffer object that is bound to the framebuffer.

• Changing the read buffer or one of the draw buffers.

• Associating a different window system-provided drawable, or no drawable, with the default framebuffer using a window system binding API such as those described in section 1.8.2.

Although the GL defines a wide variety of internal formats for framebuffer-attachable images, such as texture images and renderbuffer images, some implementations may not support rendering to particular combinations of internal formats. If the combination of formats of the images attached to a framebuffer object are not supported by the implementation, then the framebuffer is not complete under the clause labeled \texttt{FRAMEBUFFER_UNSUPPORTED}.

Implementations are required to support certain combinations of framebuffer internal formats as described under “Required Framebuffer Formats” in section 4.4.4.

Because of the \textit{implementation-dependent} clause of the framebuffer completeness test in particular, and because framebuffer completeness can change when the set of attached images is modified, it is strongly advised, though not required, that an application check to see if the framebuffer is complete prior to rendering. The status of the framebuffer object currently bound to \texttt{target} can be queried by calling

\begin{verbatim}
enum CheckFramebufferStatus( enum target );
\end{verbatim}

\texttt{target} must be \texttt{DRAW_FRAMEBUFFER}, \texttt{READ_FRAMEBUFFER}, or \texttt{FRAMEBUFFER}. \texttt{FRAMEBUFFER} is equivalent to \texttt{DRAW_FRAMEBUFFER}. If \texttt{CheckFramebufferStatus} is called within a \texttt{Begin/End} pair, an \texttt{INVALID_OPERATION} error is generated. If \texttt{CheckFramebufferStatus} generates an error, zero is returned.
Otherwise, a value is returned that identifies whether or not the framebuffer bound to target is complete, and if not complete the value identifies one of the rules of framebuffer completeness that is violated. If the framebuffer is complete, then FRAMEBUFFER_COMPLETE is returned.

The values of SAMPLE_BUFFERS and SAMPLES are derived from the attachments of the currently bound framebuffer object. If the current DRAW_FRAMEBUFFER_BINDING is not framebuffer complete, then both SAMPLE_BUFFERS and SAMPLES are undefined. Otherwise, SAMPLES is equal to the value of RENDERBUFFER_SAMPLES for the attached images (which all must have the same value for RENDERBUFFER_SAMPLES). Further, SAMPLE_BUFFERS is one if SAMPLES is non-zero. Otherwise, SAMPLE_BUFFERS is zero.

**Required Framebuffer Formats**

Implementations must support framebuffer objects with up to MAX_COLOR_ATTACHMENTS color attachments, a depth attachment, and a stencil attachment. Each color attachment may be in any of the required color formats for textures and renderbuffers described in sections 3.9.1 and 4.4.2. The depth attachment may be in any of the required depth or combined depth+stencil formats described in those sections, and the stencil attachment may be in any of the required combined depth+stencil formats.

There must be at least one default framebuffer format allowing creation of a default framebuffer supporting front-buffered rendering.

**Effects of Framebuffer Completeness on Framebuffer Operations**

Attempting to render to or read from a framebuffer which is not framebuffer complete will generate an INVALID_FRAMEBUFFER_OPERATION error. This means that rendering commands such as Begin, RasterPos, any command that performs an implicit Begin, as well as commands that read the framebuffer such as ReadPixels, CopyTexImage, and CopyTexSubImage, will generate the error INVALID_FRAMEBUFFER_OPERATION if called while the framebuffer is not framebuffer complete. This error is generated regardless of whether fragments are actually read from or written to the framebuffer. For example, it will be generated when a rendering command is called and the framebuffer is incomplete even if RASTERIZER_DISCARD is enabled.

**4.4.5 Effects of Framebuffer State on Framebuffer Dependent Values**

The values of the state variables listed in table 6.60 may change when a change is made to DRAW_FRAMEBUFFER_BINDING, to the state of the currently bound
framebuffer object, or to an image attached to the currently bound framebuffer object.

When \texttt{DRAW\_FRAMEBUFFER\_BINDING} is zero, the values of the state variables listed in table 6.60 are implementation defined.

When \texttt{DRAW\_FRAMEBUFFER\_BINDING} is non-zero, if the currently bound framebuffer object is not framebuffer complete, then the values of the state variables listed in table 6.60 are undefined.

When \texttt{DRAW\_FRAMEBUFFER\_BINDING} is non-zero and the currently bound framebuffer object is framebuffer complete, then the values of the state variables listed in table 6.60 are completely determined by \texttt{DRAW\_FRAMEBUFFER\_BINDING}, the state of the currently bound framebuffer object, and the state of the images attached to the currently bound framebuffer object. The values of \texttt{RED\_BITS}, \texttt{GREEN\_BITS}, \texttt{BLUE\_BITS}, and \texttt{ALPHA\_BITS} are defined only if all color attachments of the draw framebuffer have identical formats, in which case the color component depths of color attachment zero are returned. The values returned for \texttt{DEPTH\_BITS} and \texttt{STENCIL\_BITS} are the depth or stencil component depth of the corresponding attachment of the draw framebuffer, respectively. The actual sizes of the color, depth, or stencil bit planes can be obtained by querying an attachment point using \texttt{GetFramebufferAttachmentParameteriv}, or querying the object attached to that point. If the value of \texttt{FRAMEBUFFER\_ATTACHMENT\_OBJECT\_TYPE} at a particular attachment point is \texttt{RENDERBUFFER}, the sizes may be determined by calling \texttt{GetRenderbufferParameteriv} as described in section 6.1.3. If the value of \texttt{FRAMEBUFFER\_ATTACHMENT\_OBJECT\_TYPE} at a particular attachment point is \texttt{TEXTURE}, the sizes may be determined by calling \texttt{GetTexParameter}, as described in section 6.1.3.

### 4.4.6 Mapping between Pixel and Element in Attached Image

When \texttt{DRAW\_FRAMEBUFFER\_BINDING} is non-zero, an operation that writes to the framebuffer modifies the image attached to the selected logical buffer, and an operation that reads from the framebuffer reads from the image attached to the selected logical buffer.

If the attached image is a renderbuffer image, then the window coordinates \((x_w, y_w)\) corresponds to the value in the renderbuffer image at the same coordinates.

If the attached image is a texture image, then the window coordinates \((x_w, y_w)\) correspond to the texel \((i, j, k)\) from figure 3.10 as follows:

\[
i = (x_w - b)
\]
\[
j = (y_w - b)
\]
4.4. FRAMEBUFFER OBJECTS

\[ k = (\text{layer} - b) \]

where \( b \) is the texture image’s border width and \( \text{layer} \) is the value of \text{FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER} for the selected logical buffer. For a two-dimensional texture, \( k \) and \( \text{layer} \) are irrelevant; for a one-dimensional texture, \( j, k, \) and \( \text{layer} \) are irrelevant.

\((x_w, y_w)\) corresponds to a border texel if \( x_w, y_w, \) or \( \text{layer} \) is less than the border width, or if \( x_w, y_w, \) or \( \text{layer} \) is greater than or equal to the border width plus the width, height, or depth, respectively, of the texture image.

Conversion to Framebuffer-Attachable Image Components

When an enabled color value is written to the framebuffer while the draw framebuffer binding is non-zero, for each draw buffer the R, G, B, and A values are converted to internal components as described in table 3.16, according to the table row corresponding to the internal format of the framebuffer-attachable image attached to the selected logical buffer, and the resulting internal components are written to the image attached to logical buffer. The masking operations described in section 4.2.2 are also effective.

Conversion to RGBA Values

When a color value is read or is used as the source of a logical operation or blending while the read framebuffer binding is non-zero, the components of the framebuffer-attachable image that is attached to the logical buffer selected by \text{READ_BUFFER} are first converted to R, G, B, and A values according to table 3.25 and the internal format of the attached image.

4.4.7 Layered Framebuffers

A framebuffer is considered to be layered if it is complete and all of its populated attachments are layered. When rendering to a layered framebuffer, each fragment generated by the GL is assigned a layer number. The layer number for a fragment is zero if

- the fragment is generated by \text{DrawPixels}, \text{CopyPixels}, or \text{Bitmap},
- geometry shaders are disabled, or
- the current geometry shader does not statically assign a value to the built-in output variable \( \text{gl\_Layer} \).

</tbody>
</table>

Table 4.13: Layer numbers for cube map texture faces. The layers are numbered in the same sequence as the cube map face token values.

Otherwise, the layer for each point, line, or triangle emitted by the geometry shader is taken from the `gl_Layer` output of one of the vertices of the primitive. The vertex used is implementation-dependent. To get defined results, all vertices of each primitive emitted should set the same value for `gl_Layer`. Since the `EndPrimitive` built-in function starts a new output primitive, defined results can be achieved if `EndPrimitive` is called between two vertices emitted with different layer numbers. A layer number written by a geometry shader has no effect if the framebuffer is not layered.

When fragments are written to a layered framebuffer, the fragment’s layer number selects an image from the array of images at each attachment point to use for the stencil test (see section 4.1.5), depth buffer test (see section 4.1.6), and for blending and color buffer writes (see section 4.1.8). If the fragment’s layer number is negative, or greater than the minimum number of layers of any attachment, the effects of the fragment on the framebuffer contents are undefined.

When the `Clear` or `ClearBuffer*` commands are used to clear a layered framebuffer attachment, all layers of the attachment are cleared.

When commands such as `ReadPixels` or `CopyPixels` read from a layered framebuffer, the image at layer zero of the selected attachment is always used to obtain pixel values.

When cube map texture levels are attached to a layered framebuffer, there are six layers, numbered zero through five. Each layer number corresponds to a cube map face, as shown in table 4.13.
Chapter 5

Special Functions

This chapter describes additional GL functionality that does not fit easily into any of the preceding chapters. This functionality consists of evaluators (used to model curves and surfaces), selection (used to locate rendered primitives on the screen), feedback (which returns GL results before rasterization), display lists (used to designate a group of GL commands for later execution by the GL), flushing and finishing (used to synchronize the GL command stream), and hints.

5.1 Evaluators

Evaluators provide a means to use a polynomial or rational polynomial mapping to produce vertex, normal, and texture coordinates, and colors. The values so produced are sent on to further stages of the GL as if they had been provided directly by the client. Transformations, lighting, primitive assembly, rasterization, and per-pixel operations are not affected by the use of evaluators.

Consider the $R^k$-valued polynomial $p(u)$ defined by

$$p(u) = \sum_{i=0}^{n} B^n_i(u)R_i$$

(5.1)

with $R_i \in R^k$ and

$$B^n_i(u) = \binom{n}{i} u^i (1-u)^{n-i},$$

the $i$th Bernstein polynomial of degree $n$ (recall that $0^0 \equiv 1$ and $\binom{n}{0} \equiv 1$). Each $R_i$ is a control point. The relevant command is

```c
void Map1(fd)( enum target, T u1, T u2, int stride,
              int order, T points);
```
Table 5.1: Values specified by the target to Map1. Values are given in the order in which they are taken.

target is a symbolic constant indicating the range of the defined polynomial. Its possible values, along with the evaluations that each indicates, are given in table 5.1. order is equal to $n + 1$; The error INVALID_VALUE is generated if order is less than one or greater than MAX_EVAL_ORDER. points is a pointer to a set of $n + 1$ blocks of storage. Each block begins with $k$ single-precision floating-point or double-precision floating-point values, respectively. The rest of the block may be filled with arbitrary data. Table 5.1 indicates how $k$ depends on target and what the $k$ values represent in each case.

stride is the number of single- or double-precision values (as appropriate) in each block of storage. The error INVALID_VALUE results if stride is less than $k$. The order of the polynomial, order, is also the number of blocks of storage containing control points.

$u_1$ and $u_2$ give two floating-point values that define the endpoints of the pre-image of the map. When a value $u'$ is presented for evaluation, the formula used is

$$p'(u') = p\left(\frac{u' - u_1}{u_2 - u_1}\right).$$

The error INVALID_VALUE results if $u_1 = u_2$.

Map2 is analogous to Map1, except that it describes bivariate polynomials of the form

$$p(u, v) = \sum_{i=0}^{n} \sum_{j=0}^{m} B_i^n(u)B_j^m(v)R_{ij}.$$
5.1. EVALUATORS

The evaluation of a defined map is enabled or disabled with Enable and Disable using the constant corresponding to the map as described above. The evaluator map generates only coordinates for texture unit TEXTURE0. The error INVALID_VALUE results if either ustride or vstride is less than \( k \), or if \( u_1 \) is equal to \( u_2 \), or if \( v_1 \) is equal to \( v_2 \). If the value of ACTIVE_TEXTURE is not TEXTURE0, calling Map{12} generates the error INVALID_OPERATION.

Figure 5.1 describes map evaluation schematically; an evaluation of enabled maps is effected in one of two ways. The first way is to use

```c
void Map2{fd}( enum target, T u1, T u2, int ustride,
              int uorder, T v1, T v2, int vstride, int vorder, T points );
```

target is a range type selected from the same group as is used for Map1, except that the string MAP1 is replaced with MAP2. points is a pointer to \((n+1)(m+1)\) blocks of storage \((uorder = n + 1\) and \( vorder = m + 1\); the error INVALID_VALUE is generated if either \( uorder \) or \( vorder \) is less than one or greater than MAX_EVAL_ORDER). The values comprising \( R_{ij} \) are located

\[
ustride \times i + vstride \times j
\]

values (either single- or double-precision floating-point, as appropriate) past the first value pointed to by points. \( u_1, u_2, v_1, \) and \( v_2 \) define the pre-image rectangle of the map; a domain point \((u', v')\) is evaluated as

\[
p'(u', v') = p(\frac{u' - u_1}{u_2 - u_1}, \frac{v' - v_1}{v_2 - v_1}).
\]

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
5.1. EVALUATORS

EvalCoord1 causes evaluation of the enabled one-dimensional maps. The argument is the value (or a pointer to the value) that is the domain coordinate, \( u' \). EvalCoord2 causes evaluation of the enabled two-dimensional maps. The two values specify the two domain coordinates, \( u' \) and \( v' \), in that order.

When one of the EvalCoord commands is issued, all currently enabled maps of the indicated dimension are evaluated. Then, for each enabled map, it is as if a corresponding GL command were issued with the resulting coordinates, with one important difference. The difference is that when an evaluation is performed, the GL uses evaluated values instead of current values for those evaluations that are enabled (otherwise, the current values are used). The order of the effective commands is immaterial, except that Vertex (for vertex coordinate evaluation) must be issued last. Use of evaluators has no effect on the current color, normal, or texture coordinates. If ColorMaterial is enabled, evaluated color values affect the result of the lighting equation as if the current color was being modified, but no change is made to the tracking lighting parameters or to the current color.

No command is effectively issued if the corresponding map (of the indicated dimension) is not enabled. If more than one evaluation is enabled for a particular dimension (e.g. MAP1_TEXTURE_COORD_1 and MAP1_TEXTURE_COORD_2), then only the result of the evaluation of the map with the highest number of coordinates is used.

Finally, if either MAP2_VERTEX_3 or MAP2_VERTEX_4 is enabled, then the normal to the surface is computed. Analytic computation, which sometimes yields normals of length zero, is one method which may be used. If automatic normal generation is enabled, then this computed normal is used as the normal associated with a generated vertex. Automatic normal generation is controlled with Enable and Disable with the symbolic constant AUTO_NORMAL. If automatic normal generation is disabled, then a corresponding normal map, if enabled, is used to produce a normal. If neither automatic normal generation nor a normal map are enabled, then no normal is sent with a vertex resulting from an evaluation (the effect is that the current normal is used).

For MAP2_VERTEX_3, let \( q = p \). For MAP2_VERTEX_4, let \( q = (x/w, y/w, z/w) \), where \((x, y, z, w) = p\). Then let

\[
\mathbf{m} = \frac{\partial q}{\partial u} \times \frac{\partial q}{\partial v}.
\]

Then the generated analytic normal, \( \mathbf{n} \), is given by \( \mathbf{n} = \mathbf{m} \) if a vertex shader is active, or else by \( \mathbf{n} = \frac{\mathbf{m}}{||\mathbf{m}||} \).

The second way to carry out evaluations is to use a set of commands that provide for efficient specification of a series of evenly spaced values to be mapped. This method proceeds in two steps. The first step is to define a grid in the domain.
This is done using

```c
void MapGrid1(fd)(int n, T u'_1, T u'_2);
```
for a one-dimensional map or

```c
void MapGrid2(fd)(int n_u, T u'_1, T u'_2, int n_v, T v'_1, T v'_2);
```
for a two-dimensional map. In the case of `MapGrid1`, `u'_1` and `u'_2` describe an interval, while `n` describes the number of partitions of the interval. The error `INVALID_VALUE` results if `n ≤ 0`. For `MapGrid2`, `(u'_1, v'_1)` specifies one two-dimensional point and `(u'_2, v'_2)` specifies another. `n_u` gives the number of partitions between `u'_1` and `u'_2`, and `n_v` gives the number of partitions between `v'_1` and `v'_2`. If either `n_u ≤ 0` or `n_v ≤ 0`, then the error `INVALID_VALUE` occurs.

Once a grid is defined, an evaluation on a rectangular subset of that grid may be carried out by calling

```c
void EvalMesh1(enum mode, int p1, int p2);
```
`mode` is either `POINT` or `LINE`. The effect is the same as performing the following code fragment, with \( \Delta u' = (u'_2 - u'_1)/n \):

```
Begin (type);
for i = p1 to p2 step 1.0
    EvalCoord1 (i * \Delta u' + u'_1);
End () ;
```
where `EvalCoord1f` or `EvalCoord1d` is substituted for `EvalCoord1` as appropriate. If `mode` is `POINT`, then `type` is `POINTS`; if `mode` is `LINE`, then `type` is `LINE_STRIP`. The one requirement is that if either \( i = 0 \) or \( i = n \), then the value computed from \( i * \Delta u' + u'_1 \) is precisely `u'_1` or `u'_2`, respectively.

The corresponding commands for two-dimensional maps are

```c
void EvalMesh2(enum mode, int p1, int p2, int q1, int q2);
```
`mode` must be `FILL`, `LINE`, or `POINT`. When `mode` is `FILL`, then these commands are equivalent to the following, with \( \Delta u' = (u'_2 - u'_1)/n \) and \( \Delta v' = (v'_2 - v'_1)/m \):
for $i = q_1$ to $q_2 - 1$ step 1.0
Begin (QUAD_STRIP);
for $j = p_1$ to $p_2$ step 1.0
  EvalCoord2 ($j \times \Delta u' + u'_1$, $i \times \Delta v' + v'_1$);
  EvalCoord2 ($j \times \Delta u' + u'_1$, $(i+1) \times \Delta v' + v'_1$);
End (;);

If mode is LINE, then a call to EvalMesh2 is equivalent to

for $i = q_1$ to $q_2$ step 1.0
Begin (LINE_STRIP);
for $j = p_1$ to $p_2$ step 1.0
  EvalCoord2 ($j \times \Delta u' + u'_1$, $i \times \Delta v' + v'_1$);
End (;);
for $i = p_1$ to $p_2$ step 1.0
Begin (LINE_STRIP);
for $j = q_1$ to $q_2$ step 1.0
  EvalCoord2 ($i \times \Delta u' + u'_1$, $j \times \Delta v' + v'_1$);
End (;);

If mode is POINT, then a call to EvalMesh2 is equivalent to

Begin (POINTS);
for $i = q_1$ to $q_2$ step 1.0
for $j = p_1$ to $p_2$ step 1.0
  EvalCoord2 ($j \times \Delta u' + u'_1$, $i \times \Delta v' + v'_1$);
End (;);

Again, in all three cases, there is the requirement that $0 \times \Delta u' + u'_1 = u'_1$, $n \times \Delta u' + u'_1 = u'_2$, $0 \times \Delta v' + v'_1 = v'_1$, and $m \times \Delta v' + v'_1 = v'_2$.

An evaluation of a single point on the grid may also be carried out:

void EvalPoint1(int $p$);

Calling it is equivalent to the command

EvalCoord1 ($p \times \Delta u' + u'_1$);

with $\Delta u'$ and $u'_1$ defined as above.

void EvalPoint2(int $p$, int $q$);

is equivalent to the command

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
EvalCoord2 \( (p \ast \Delta u' + u'_1, q \ast \Delta v' + v'_1) \);

The state required for evaluators potentially consists of 9 one-dimensional map specifications and 9 two-dimensional map specifications, as well as corresponding flags for each specification indicating which are enabled. Each map specification consists of one or two orders, an appropriately sized array of control points, and a set of two values (for a one-dimensional map) or four values (for a two-dimensional map) to describe the domain. The maximum possible order, for either \( u \) or \( v \), is implementation-dependent (one maximum applies to both \( u \) and \( v \)), but must be at least 8. Each control point consists of between one and four floating-point values (depending on the type of the map). Initially, all maps have order 1 (making them constant maps). All vertex coordinate maps produce the coordinates \((0, 0, 0, 1)\) (or the appropriate subset); all normal coordinate maps produce \((0, 0, 1)\); RGBA maps produce \((1, 1, 1, 1)\); color index maps produce 1.0; and texture coordinate maps produce \((0, 0, 1)\). In the initial state, all maps are disabled. A flag indicates whether or not automatic normal generation is enabled for two-dimensional maps. In the initial state, automatic normal generation is disabled. Also required are two floating-point values and an integer number of grid divisions for the one-dimensional grid specification and four floating-point values and two integer grid divisions for the two-dimensional grid specification. In the initial state, the bounds of the domain interval for 1-D is \([0, 1]\), respectively; for 2-D, they are \([0, 0, 1, 0, 1]\), respectively. The number of grid divisions is 1 for 1-D and 1 in both directions for 2-D. If any evaluation command is issued when no vertex map is enabled for the map dimension being evaluated, nothing happens.

### 5.2 Selection

Selection is used to determine which primitives are drawn into some region of a window. The region is defined by the current model-view and perspective matrices.

Selection works by returning an array of integer-valued names. This array represents the current contents of the name stack. This stack is controlled with the commands

```c
void InitNames( void );
void PopName( void );
void PushName( uint name );
void LoadName( uint name );
```

InitNames empties (clears) the name stack. PopName pops one name off the top of the name stack. PushName causes name to be pushed onto the name stack.
5.2. **SELECTION**

*LoadName* replaces the value on the top of the stack with *name*. Loading a name onto an empty stack generates the error `INVALID_OPERATION`. Popping a name off of an empty stack generates `STACK_UNDERFLOW`; pushing a name onto a full stack generates `STACK_OVERFLOW`. The maximum allowable depth of the name stack is implementation-dependent but must be at least 64.

In selection mode, framebuffer updates as described in chapter 4 are not performed. The GL is placed in selection mode with

```c
int  RenderMode( enum mode );
```

*mode* is a symbolic constant: one of `RENDER`, `SELECT`, or `FEEDBACK`. `RENDER` is the default, corresponding to rendering as described until now. `SELECT` specifies selection mode, and `FEEDBACK` specifies feedback mode (described below). Use of any of the name stack manipulation commands while the GL is not in selection mode has no effect.

Selection is controlled using

```c
void  SelectBuffer( sizei n, uint *buffer );
```

*buffer* is a pointer to an array of unsigned integers (called the selection array) to be potentially filled with names, and *n* is an integer indicating the maximum number of values that can be stored in that array. Placing the GL in selection mode before `SelectBuffer` has been called results in an error of `INVALID_OPERATION` as does calling `SelectBuffer` while in selection mode.

In selection mode, if a point, line, polygon, or the valid coordinates produced by a `RasterPos` command intersects the clip volume (section 2.22) then this primitive (or `RasterPos` command) causes a selection *hit*. `WindowPos` commands always generate a selection hit, since the resulting raster position is always valid. In the case of polygons, no hit occurs if the polygon would have been culled, but selection is based on the polygon itself, regardless of the setting of `PolygonMode`. When in selection mode, whenever a name stack manipulation command is executed or `RenderMode` is called and there has been a hit since the last time the stack was manipulated or `RenderMode` was called, then a *hit record* is written into the selection array.

A hit record consists of the following items in order: a non-negative integer giving the number of elements on the name stack at the time of the hit, a minimum depth value, a maximum depth value, and the name stack with the bottommost element first. The minimum and maximum depth values are the minimum and maximum taken over all the window coordinate *z* values of each (post-clipping) vertex of each primitive that intersects the clipping volume since the last hit record was
written. The minimum and maximum (each of which lies in the range $[0, 1]$) are each multiplied by $2^{32} - 1$ and rounded to the nearest unsigned integer to obtain the values that are placed in the hit record. No depth offset arithmetic (section 3.6.5) is performed on these values.

Hit records are placed in the selection array by maintaining a pointer into that array. When selection mode is entered, the pointer is initialized to the beginning of the array. Each time a hit record is copied, the pointer is updated to point at the array element after the one into which the topmost element of the name stack was stored. If copying the hit record into the selection array would cause the total number of values to exceed $n$, then as much of the record as fits in the array is written and an overflow flag is set.

Selection mode is exited by calling `RenderMode` with an argument value other than `SELECT`. When called while in selection mode, `RenderMode` returns the number of hit records copied into the selection array and resets the `SelectBuffer` pointer to its last specified value. Values are not guaranteed to be written into the selection array until `RenderMode` is called. If the selection array overflow flag was set, then `RenderMode` returns $-1$ and clears the overflow flag. The name stack is cleared and the stack pointer reset whenever `RenderMode` is called.

The state required for selection consists of the address of the selection array and its maximum size, the name stack and its associated pointer, a minimum and maximum depth value, and several flags. One flag indicates the current `RenderMode` value. In the initial state, the GL is in the `RENDER` mode. Another flag is used to indicate whether or not a hit has occurred since the last name stack manipulation. This flag is reset upon entering selection mode and whenever a name stack manipulation takes place. One final flag is required to indicate whether the maximum number of copied names would have been exceeded. This flag is reset upon entering selection mode. This flag, the address of the selection array, and its maximum size are GL client state.

### 5.3 Feedback

The GL is placed in feedback mode by calling `RenderMode` with `FEEDBACK`. When in feedback mode, framebuffer updates as described in chapter 4 are not performed. Instead, information about primitives that would have otherwise been rasterized is returned to the application via the `feedback buffer`.

Feedback is controlled using

```c
void FeedbackBuffer(sizei n, enum type, float *buffer);
```
buffer is a pointer to an array of floating-point values into which feedback information will be placed, and \( n \) is a number indicating the maximum number of values that can be written to that array. \( \text{type} \) is a symbolic constant describing the information to be fed back for each vertex (see figure 5.2). The error INVALID_OPERATION results if the GL is placed in feedback mode before a call to \text{FeedbackBuffer} has been made, or if a call to \text{FeedbackBuffer} is made while in feedback mode.

While in feedback mode, each primitive that would be rasterized (or bitmap or call to \text{DrawPixels} or \text{CopyPixels}, if the raster position is valid) generates a block of values that get copied into the feedback array. If doing so would cause the number of entries to exceed the maximum, the block is partially written so as to fill the array (if there is any room left at all). The first block of values generated after the GL enters feedback mode is placed at the beginning of the feedback array, with subsequent blocks following. Each block begins with a code indicating the primitive type, followed by values that describe the primitive’s vertices and associated data. Entries are also written for bitmaps and pixel rectangles. Feedback occurs after polygon culling (section 3.6.1) and \text{PolygonMode} interpretation of polygons (section 3.6.4) has taken place. It may also occur after polygons with more than three edges are broken up into triangles (if the GL implementation renders polygons by performing this decomposition). \( x, y, \) and \( z \) coordinates returned by feedback are window coordinates; if \( w \) is returned, it is in clip coordinates. No depth offset arithmetic (section 3.6.5) is performed on the \( z \) values. In the case of bitmaps and pixel rectangles, the coordinates returned are those of the current raster position.

The texture coordinates and colors returned are those resulting from the clipping operations described in section 2.22.1. Only coordinates for texture unit TEXTURE0 are returned even for implementations which support multiple texture units. The colors returned are the primary colors.

The ordering rules for GL command interpretation also apply in feedback mode. Each command must be fully interpreted and its effects on both GL state and the values to be written to the feedback buffer completed before a subsequent command may be executed.

Feedback mode is exited by calling \text{RenderMode} with an argument value other than \text{FEEDBACK}. When called while in feedback mode, \text{RenderMode} returns the number of values placed in the feedback array and resets the feedback array pointer to be \text{buffer}. The return value never exceeds the maximum number of values passed to \text{FeedbackBuffer}.

If writing a value to the feedback buffer would cause more values to be written than the specified maximum number of values, then the value is not written and an overflow flag is set. In this case, \text{RenderMode} returns \(-1\) when it is called, after

which the overflow flag is reset. While in feedback mode, values are not guaranteed to be written into the feedback buffer before RenderMode is called.

Figure 5.2 gives a grammar for the array produced by feedback. Each primitive is indicated with a unique identifying value followed by some number of vertices. A vertex is fed back as some number of floating-point values determined by the feedback type. Table 5.2 gives the correspondence between type and the number of values returned for each vertex.

The command

```
void PassThrough(float token);
```

may be used as a marker in feedback mode. token is returned as if it were a primitive; it is indicated with its own unique identifying value. The ordering of any PassThrough commands with respect to primitive specification is maintained by feedback. PassThrough may not occur between Begin and End. It has no effect when the GL is not in feedback mode.

The state required for feedback is the pointer to the feedback array, the maximum number of values that may be placed there, and the feedback type. An overflow flag is required to indicate whether the maximum allowable number of feedback values has been written; initially this flag is cleared. These state variables are GL client state. Feedback also relies on the same mode flag as selection to indicate whether the GL is in feedback, selection, or normal rendering mode.

5.4 Display Lists

A display list is simply a group of GL commands and arguments that has been stored for subsequent execution. The GL may be instructed to process a particular display list (possibly repeatedly) by providing a number that uniquely specifies it. Doing so causes the commands within the list to be executed just as if they were

Figure 5.2: Feedback syntax. \( f \) is a floating-point number. \( n \) is a floating-point integer giving the number of vertices in a polygon. The symbols ending with _TOKEN are symbolic floating-point constants. The labels under the “vertex” rule show the different data returned for vertices depending on the feedback type. LINE_TOKEN and LINE_RESET_TOKEN are identical except that the latter is returned only when the line stipple is reset for that line segment.
given normally. The only exception pertains to commands that rely upon client state. When such a command is accumulated into the display list (that is, when issued, not when executed), the client state in effect at that time applies to the command. Only server state is affected when the command is executed. As always, pointers which are passed as arguments to commands are dereferenced when the command is issued. (Vertex array pointers are dereferenced when the commands `ArrayElement`, `DrawArrays`, `DrawElements`, or `DrawRangeElements` are accumulated into a display list.)

A display list is begun by calling

```c
void NewList( uint n, enum mode );
```

\(n\) is a positive integer to which the display list that follows is assigned, and \(mode\) is a symbolic constant that controls the behavior of the GL during display list creation. If \(mode\) is `COMPILE`, then commands are not executed as they are placed in the display list. If \(mode\) is `COMPILE_AND_EXECUTE` then commands are executed as they are encountered, then placed in the display list. If \(n = 0\), then the error `INVALID_VALUE` is generated.

After calling `NewList` all subsequent GL commands are placed in the display list (in the order the commands are issued) until a call to

```c
void EndList( void );
```

occurs, after which the GL returns to its normal command execution state. It is only when `EndList` occurs that the specified display list is actually associated with the index indicated with `NewList`. The error `INVALID_OPERATION` is generated if `EndList` is called without a previous matching `NewList`, or if `NewList` is called a second time before calling `EndList`. The error `OUT_OF_MEMORY` is generated if `EndList` is called and the specified display list cannot be stored because insufficient memory is available. In this case GL implementations of revision 1.1 or greater insure that no change is made to the previous contents of the display list, if any, and that no other change is made to the GL state, except for the state changed by execution of GL commands when the display list mode is `COMPILE_AND_EXECUTE`.

Once defined, a display list is executed by calling

```c
void CallList( uint n );
```

\(n\) gives the index of the display list to be called. This causes the commands saved in the display list to be executed, in order, just as if they were issued without using a display list. If \(n = 0\), then the error `INVALID_VALUE` is generated.

The command
5.4. **DISPLAY LISTS**

```c
void CallLists(sizei n, enum type, void* lists);
```

provides an efficient means for executing a number of display lists. *n* is an integer indicating the number of display lists to be called, and *lists* is a pointer that points to an array of offsets. Each offset is constructed as determined by *lists* as follows. First, *type* may be one of the constants `BYTE`, `UNSIGNED_BYTE`, `SHORT`, `UNSIGNED_SHORT`, `INT`, `UNSIGNED_INT`, or `FLOAT` indicating that the array pointed to by *lists* is an array of bytes, unsigned bytes, shorts, unsigned shorts, integers, unsigned integers, or floats, respectively. In this case each offset is found by simply converting each array element to an integer (floating point values are truncated to negative infinity). Further, *type* may be one of `2_BYTES`, `3_BYTES`, or `4_BYTES`, indicating that the array contains sequences of 2, 3, or 4 unsigned bytes, in which case each integer offset is constructed according to the following algorithm:

```c
offset ← 0
for i = 1 to b
    offset ← offset shifted left 8 bits
    offset ← offset + byte
    advance to next byte in the array
```

*b* is 2, 3, or 4, as indicated by *type*. If *n* = 0, `CallLists` does nothing.

Each of the *n* constructed offsets is taken in order and added to a display list base to obtain a display list number. For each number, the indicated display list is executed. The base is set by calling

```c
void ListBase(uint base);
```

to specify the offset.

Indicating a display list index that does not correspond to any display list has no effect. `CallList` or `CallLists` may appear inside a display list. (If the `mode` supplied to `NewList` is `COMPILE_AND_EXECUTE`, then the appropriate lists are executed, but the `CallList` or `CallLists`, rather than those lists’ constituent commands, is placed in the list under construction.) To avoid the possibility of infinite recursion resulting from display lists calling one another, an implementation-dependent limit is placed on the nesting level of display lists during display list execution. This limit must be at least 64.

Two commands are provided to manage display list indices.

```c
uint GenLists(sizei s);
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
returns an integer $n$ such that the indices $n, \ldots, n+s-1$ are previously unused (i.e.
there are $s$ previously unused display list indices starting at $n$). \texttt{GenLists} also has
the effect of creating an empty display list for each of the indices $n, \ldots, n+s-1$,
so that these indices all become used. \texttt{GenLists} returns 0 if there is no group of $s$
contiguous previously unused display list indices, or if $s = 0$.

    boolean IsList( uint list );

returns TRUE if \texttt{list} is the index of some display list.
A contiguous group of display lists may be deleted by calling

    void DeleteLists( uint list, sizei range );

where \texttt{list} is the index of the first display list to be deleted and \texttt{range} is the number
of display lists to be deleted. All information about the display lists is lost, and the
indices become unused. Indices to which no display list corresponds are ignored.
If \texttt{range} = 0, nothing happens.

5.4.1 Commands Not Usable In Display Lists

Certain commands, when called while compiling a display list, are not compiled
into the display list but are executed immediately. These commands fall in several
categories including

- \textit{Display lists}: \texttt{GenLists} and \texttt{DeleteLists}.
- \textit{Render modes}: \texttt{FeedbackBuffer}, \texttt{SelectBuffer}, and \texttt{RenderMode}.
- \textit{Vertex arrays}: \texttt{ClientActiveTexture}, \texttt{ColorPointer}, \texttt{EdgeFlagPointer}, \texttt{Fog-
CoordPointer}, \texttt{IndexPointer}, \texttt{InterleavedArrays}, \texttt{NormalPointer}, \texttt{Secondary-
ColorPointer}, \texttt{TexCoordPointer}, \texttt{VertexAttribPointer}, \texttt{VertexAttribIPointer}, \texttt{Vertex-
Pointer}, \texttt{PrimitiveRestartIndex}, \texttt{GenVertexArrays}, \texttt{DeleteVertexAr-
rays}, and \texttt{BindVertexArray}.
- \textit{Client state}: \texttt{EnableClientState}, \texttt{DisableClientState}, \texttt{EnableVertexAttrib-
Array}, \texttt{DisableVertexAttribArray}, \texttt{PushClientAttrib}, and \texttt{PopClientAttrib}.
- \textit{Pixels and textures}: \texttt{PixelStore}, \texttt{ReadPixels}, \texttt{GenTextures}, \texttt{DeleteTextures},
\texttt{AreTexturesResident}, \texttt{TexBuffer}, and \texttt{GenerateMipmap}.
- \textit{Occlusion queries}: \texttt{GenQueries} and \texttt{DeleteQueries}.
- \textit{Buffer objects}: \texttt{GenBuffers}, \texttt{DeleteBuffers}, \texttt{BindBuffer}, \texttt{BindBuffer-
Range}, \texttt{BindBufferBase}, \texttt{TransformFeedbackVaryings}, \texttt{BufferData}, \texttt{Buffer-
SubData}, \texttt{MapBuffer}, \texttt{MapBufferRange}, \texttt{FlushMappedBufferRange}, and \texttt{Un-
mapBuffer}.
- \textit{Framebuffer and renderbuffer objects}: \texttt{GenFramebuffers}, \texttt{BindFrame-
buffer}, \texttt{DeleteFramebuffers}, \texttt{CheckFramebufferStatus}, \texttt{GenRenderbuffers},
5.4. DISPLAY LISTS

Program and shader objects: CreateProgram, CreateShader,DeleteProgram, DeleteShader, AttachShader, DetachShader, BindAttribLocation, BindFragDataLocation, CompileShader, ShaderSource, LinkProgram, and ValidateProgram.

Other queries: All query commands whose names begin with Get and Is (see chapter 6).

GL commands that source data from buffer objects dereference the buffer object data in question at display list compile time, rather than encoding the buffer ID and buffer offset into the display list. Only GL commands that are executed immediately, rather than being compiled into a display list, are permitted to use a buffer object as a data sink.

TexImage3D, TexImage2D, TexImage1D, Histogram, and ColorTable are executed immediately when called with the corresponding proxy arguments PROXY_TEXTURE_3D or PROXY_TEXTURE_2D_ARRAY; PROXY_TEXTURE_2D PROXY_TEXTURE_1D_ARRAY, or PROXY_TEXTURE_CUBE_MAP; PROXY_TEXTURE_1D; PROXY_HISTOGRAM; and PROXY_COLOR_TABLE, PROXY_POST_CONVOLUTION_COLOR_TABLE, or PROXY_POST_COLOR_MATRIX_COLOR_TABLE.

When a program object is in use, a display list may be executed whose vertex attribute calls do not match up exactly with what is expected by the vertex shader contained in that program object. Handling of this mismatch is described in section 2.14.3.

Display lists require one bit of state to indicate whether a GL command should be executed immediately or placed in a display list. In the initial state, commands are executed immediately. If the bit indicates display list creation, an index is required to indicate the current display list being defined. Another bit indicates, during display list creation, whether or not commands should be executed as they are compiled into the display list. One integer is required for the current ListBase setting; its initial value is zero. Finally, state must be maintained to indicate which integers are currently in use as display list indices. In the initial state, no indices are in use.
5.5 Flush and Finish

The command

```c
void Flush(void);
```

indicates that all commands that have previously been sent to the GL must complete in finite time.

The command

```c
void Finish(void);
```

forces all previous GL commands to complete. `Finish` does not return until all effects from previously issued commands on GL client and server state and the framebuffer are fully realized.

5.6 Sync Objects and Fences

Sync objects act as a synchronization primitive - a representation of events whose completion status can be tested or waited upon. Sync objects may be used for synchronization with operations occurring in the GL state machine or in the graphics pipeline, and for synchronizing between multiple graphics contexts, among other purposes.

Sync objects have a status value with two possible states: `signaled` and `unsignaled`. Events are associated with a sync object. When a sync object is created, its status is set to unsignaled. When the associated event occurs, the sync object is signaled (its status is set to signaled). The GL may be asked to wait for a sync object to become signaled.

Initially, only one specific type of sync object is defined: the fence sync object, whose associated event is triggered by a fence command placed in the GL command stream. Fence sync objects are used to wait for partial completion of the GL command stream, as a more flexible form of `Finish`.

The command

```c
sync FenceSync(enum condition, bitfield flags);
```

creates a new fence sync object, inserts a fence command in the GL command stream and associates it with that sync object, and returns a non-zero name corresponding to the sync object.
5.6. SYNC OBJECTS AND FENCES

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Value</th>

<tr>
<td>SYNC_STATUS</td>
<td>UNSIGNALED</td>
</tr>
<tr>
<td>SYNC_FLAGS</td>
<td>flags</td>
</tr>
</tbody>
</table>

Table 5.3: Initial properties of a sync object created with FenceSync.

When the specified condition of the sync object is satisfied by the fence command, the sync object is signaled by the GL, causing any ClientWaitSync or WaitSync commands (see below) blocking on sync to unblock. No other state is affected by FenceSync or by execution of the associated fence command.

condition must be SYNC_GPU_COMMANDS_COMPLETE. This condition is satisfied by completion of the fence command corresponding to the sync object and all preceding commands in the same command stream. The sync object will not be signaled until all effects from these commands on GL client and server state and the framebuffer are fully realized. Note that completion of the fence command occurs once the state of the corresponding sync object has been changed, but commands waiting on that sync object may not be unblocked until after the fence command completes.

flags must be 0.

Each sync object contains a number of properties which determine the state of the object and the behavior of any commands associated with it. Each property has a property name and property value. The initial property values for a sync object created by FenceSync are shown in table 5.3.

Properties of a sync object may be queried with GetSynciv (see section 6.1.13). The SYNC_STATUS property will be changed to SIGNALED when condition is satisfied.

If FenceSync fails to create a sync object, zero will be returned and a GL error will be generated as described. An INVALID_ENUM error is generated if condition is not SYNC_GPU_COMMANDS_COMPLETE. If flags is not zero, an INVALID_VALUE error is generated.

A sync object can be deleted by passing its name to the command

```
void DeleteSync( sync sync );
```

If the fence command corresponding to the specified sync object has completed, or if no ClientWaitSync or WaitSync commands are blocking on sync, the

---

1 flags is a placeholder for anticipated future extensions of fence sync object capabilities.
object is deleted immediately. Otherwise, \textit{sync} is flagged for deletion and will be deleted when it is no longer associated with any fence command and is no longer blocking any \texttt{ClientWaitSync} or \texttt{WaitSync} command. In either case, after returning from \texttt{DeleteSync} the \textit{sync} name is invalid and can no longer be used to refer to the sync object.

\texttt{DeleteSync} will silently ignore a \textit{sync} value of zero. An \texttt{INVALID_VALUE} error is generated if \textit{sync} is neither zero nor the name of a sync object.

\subsection*{5.6.1 Waiting for Sync Objects}

The command

\begin{verbatim}
enum ClientWaitSync( sync sync, bitfield flags,  
    uint64 timeout );
\end{verbatim}

causes the GL to block, and will not return until the sync object \textit{sync} is signaled, or until the specified \textit{timeout} period expires. \textit{timeout} is in units of nanoseconds. \textit{timeout} is adjusted to the closest value allowed by the implementation-dependent timeout accuracy, which may be substantially longer than one nanosecond, and may be longer than the requested period.

If \textit{sync} is signaled at the time \texttt{ClientWaitSync} is called, then \texttt{ClientWaitSync} returns immediately. If \textit{sync} is unsignaled at the time \texttt{ClientWaitSync} is called, then \texttt{ClientWaitSync} will block and will wait up to \textit{timeout} nanoseconds for \textit{sync} to become signaled. \textit{flags} controls command flushing behavior, and may be \texttt{SYNC_FLUSH_COMMANDS_BIT}, as discussed in section 5.6.2.

\texttt{ClientWaitSync} returns one of four status values. A return value of \texttt{ALREADY_SIGNALED} indicates that \textit{sync} was signaled at the time \texttt{ClientWaitSync} was called. \texttt{ALREADY_SIGNALED} will always be returned if \textit{sync} was signaled, even if the value of \textit{timeout} is zero. A return value of \texttt{TIMEOUT_EXPIRED} indicates that the specified timeout period expired before \textit{sync} was signaled. A return value of \texttt{CONDITION_SATISFIED} indicates that \textit{sync} was signaled before the timeout expired. Finally, if an error occurs, in addition to generating a GL error as specified below, \texttt{ClientWaitSync} immediately returns \texttt{WAIT_FAILED} without blocking.

If the value of \textit{timeout} is zero, then \texttt{ClientWaitSync} does not block, but simply tests the current state of \textit{sync}. \texttt{TIMEOUT_EXPIRED} will be returned in this case if \textit{sync} is not signaled, even though no actual wait was performed.

If \textit{sync} is not the name of a sync object, an \texttt{INVALID_VALUE} error is generated. If \textit{flags} contains any bits other than \texttt{SYNC_FLUSH_COMMANDS_BIT}, an \texttt{INVALID_VALUE} error is generated.

The command
void WaitSync(s sync sync, bitfield flags, uint64 timeout);

is similar to ClientWaitSync, but instead of blocking and not returning to the application until sync is signaled, WaitSync returns immediately, instead causing the GL server to block 2 until sync is signaled 3.

sync has the same meaning as for ClientWaitSync.

timeout must currently be the special value TIMEOUT_IGNORED, and is not used. Instead, WaitSync will always wait no longer than an implementation-dependent timeout. The duration of this timeout in nanoseconds may be queried by calling GetInteger64v with value MAX_SERVER_WAIT_TIMEOUT. There is currently no way to determine whether WaitSync unblocked because the timeout expired or because the sync object being waited on was signaled.

flags must be 0.

If an error occurs, WaitSync generates a GL error as specified below, and does not cause the GL server to block.

If sync is not the name of a sync object, an INVALID_VALUE error is generated.

If timeout is not TIMEOUT_IGNORED or flags is not zero, an INVALID_VALUE error is generated 4.

Multiple Waiters

It is possible for both the GL client to be blocked on a sync object in a ClientWaitSync command, the GL server to be blocked as the result of a previous WaitSync command, and for additional WaitSync commands to be queued in the GL server, all for a single sync object. When such a sync object is signaled in this situation, the client will be unblocked, the server will be unblocked, and all such queued WaitSync commands will continue immediately when they are reached.

See appendix D.2 for more information about blocking on a sync object in multiple GL contexts.

2The GL server may choose to wait either in the CPU executing server-side code, or in the GPU hardware if it supports this operation.

3WaitSync allows applications to continue to queue commands from the client in anticipation of the sync being signalled, increasing client-server parallelism.

4flags and timeout are placeholders for anticipated future extensions of sync object capabilities. They must have these reserved values in order that existing code calling WaitSync operate properly in the presence of such extensions.
5.7 HINTS

5.6.2 Signalling

A fence sync object enters the signalled state only once the corresponding fence command has completed and signalled the sync object.

If the sync object being blocked upon will not be signalled in finite time (for example, by an associated fence command issued previously, but not yet flushed to the graphics pipeline), then ClientWaitSync may hang forever. To help prevent this behavior, if the SYNC_FLUSH_COMMANDS_BIT bit is set in flags, and sync is unsignaled when ClientWaitSync is called, then the equivalent of Flush will be performed before blocking on sync.

If a sync object is marked for deletion while a client is blocking on that object in a ClientWaitSync command, or a GL server is blocking on that object as a result of a prior WaitSync command, deletion is deferred until the sync object is signalled and all blocked GL clients and servers are unblocked.

Additional constraints on the use of sync objects are discussed in appendix D. State must be maintained to indicate which sync object names are currently in use. The state require for each sync object in use is an integer for the specific type, an integer for the condition, and a bit indicating whether the object is signalled or unsignalled. The initial values of sync object state are defined as specified by FenceSync.

5.7 Hints

Certain aspects of GL behavior, when there is room for variation, may be controlled with hints. A hint is specified using

```c
void Hint( enum target, enum hint );
```

target is a symbolic constant indicating the behavior to be controlled, and hint is a symbolic constant indicating what type of behavior is desired. The possible targets are described in table 5.4; for each target, hint must be one of FASTEST, indicating that the most efficient option should be chosen; NICEST, indicating that the highest quality option should be chosen; and DONT_CARE, indicating no preference in the matter.

For the texture compression hint, a hint of FASTEST indicates that texture images should be compressed as quickly as possible, while NICEST indicates that

---

5The simple flushing behavior defined by SYNC_FLUSH_COMMANDS_BIT will not help when waiting for a fence command issued in another context’s command stream to complete. Applications which block on a fence sync object must take additional steps to assure that the context from which the corresponding fence command was issued has flushed that command to the graphics pipeline.
the texture images be compressed with as little image degradation as possible. **FASTEST** should be used for one-time texture compression, and **NICEST** should be used if the compression results are to be retrieved by `GetCompressedTexImage` (section 6.1.4) for reuse.

The interpretation of hints is implementation-dependent. An implementation may ignore them entirely.

The initial value of all hints is **DONT_CARE**.

Chapter 6

State and State Requests

The state required to describe the GL machine is enumerated in section 6.2. Most state is set through the calls described in previous chapters, and can be queried using the calls described in section 6.1.

6.1 Querying GL State

6.1.1 Simple Queries

Much of the GL state is completely identified by symbolic constants. The values of these state variables can be obtained using a set of Get commands. There are four commands for obtaining simple state variables:

```c
void GetBooleanv( enum value, boolean *data );
void GetIntegerv( enum value, int *data );
void GetInteger64v( enum value, int64 *data );
void GetFloatv( enum value, float *data );
void GetDoublev( enum value, double *data );
```

The commands obtain boolean, integer, 64-bit integer, floating-point, or double-precision state variables. `value` is a symbolic constant indicating the state variable to return. `data` is a pointer to a scalar or array of the indicated type in which to place the returned data.

Indexed simple state variables are queried with the commands

```c
void GetBooleani_v( enum target, uint index, boolean *data );
void GetIntegeri_v( enum target, uint index, int *data );
```
6.1. QUERYING GL STATE

```c
void GetInteger64i_v( enum target, uint index, int64 *data );
```

target is the name of the indexed state and index is the index of the particular element being queried. data is a pointer to a scalar or array of the indicated type in which to place the returned data. An INVALID_VALUE error is generated if index is outside the valid range for the indexed state target.

Finally,

```c
boolean IsEnabled( enum value );
```

can be used to determine if value is currently enabled (as with Enable) or disabled, and

```c
boolean IsEnabledi( enum target, uint index );
```

can be used to determine if the indexed state corresponding to target and index is enabled or disabled. An INVALID_VALUE error is generated if index is outside the valid range for the indexed state target.

6.1.2 Data Conversions

If a Get command is issued that returns value types different from the type of the value being obtained, a type conversion is performed. If GetBooleanv is called, a floating-point or integer value converts to FALSE if and only if it is zero (otherwise it converts to TRUE). If any of the other simple queries are called, a boolean value of TRUE or FALSE is interpreted as 1 or 0, respectively. If GetIntegerv or GetInteger64v are called, a floating-point value is rounded to the nearest integer, unless the value is an RGBA color component, a normal coordinate, a DepthRange value, or a depth buffer clear value. In these cases, the Get command converts the floating-point value to an integer according to the INT entry of table 4.9; a value not in [−1, 1] converts to an undefined value. If GetFloatv is called, a boolean value of TRUE or FALSE is interpreted as 1.0 or 0.0, respectively, an integer is coerced to floating-point, and a double-precision floating-point value is converted to single-precision. Analogous conversions are carried out in the case of GetDoublev. If a value is so large in magnitude that it cannot be represented with the requested type, then the nearest value representable using the requested type is returned.

Unless otherwise indicated, multi-valued state variables return their multiple values in the same order as they are given as arguments to the commands that set them. For instance, the two DepthRange parameters are returned in the order n followed by f. Similarly, points for evaluator maps are returned in the order that...
they appeared when passed to Map1. Map2 returns $R_{ij}$ in the $[(uorder)i + j]$th block of values (see page 345 for $i$, $j$, $uorder$, and $R_{ij}$).

Matrices may be queried and returned in transposed form by calling Get-Booleanv, GetIntegerv, GetFloatv, and GetDoublev with $pname$ set to one of TRANSPOSE_MODELVIEW_MATRIX, TRANSPOSE_PROJECTION_MATRIX, TRANSPOSE_TEXTURE_MATRIX, or TRANSPOSE_COLOR_MATRIX. The effect of

\[
\text{GetFloatv} \left( \text{TRANSPOSE_MODELVIEW_MATRIX}, m \right);
\]

is the same as the effect of the command sequence

\[
\text{GetFloatv} \left( \text{MODELVIEW_MATRIX}, m \right);
\]

\[
m = m^T;
\]

Similar conversions occur when querying TRANSPOSE_PROJECTION_MATRIX, TRANSPOSE_TEXTURE_MATRIX, and TRANSPOSE_COLOR_MATRIX.

If fragment color clamping is enabled, querying of the texture border color, texture environment color, fog color, alpha test reference value, blend color, and RGBA clear color will clamp the corresponding state values to $[0, 1]$ before returning them. This behavior provides compatibility with previous versions of the GL that clamped these values when specified.

Most texture state variables are qualified by the value of ACTIVE_TEXTURE to determine which server texture state vector is queried. Client texture state variables such as texture coordinate array pointers are qualified by the value of client_ACTIVE_TEXTURE. Tables 6.6, 6.7, 6.13, 6.20, 6.24, and 6.52 indicate Table 6.20 indicates those state variables which are qualified by ACTIVE_TEXTURE or client_ACTIVE_TEXTURE during state queries. Queries of texture state variables corresponding to texture coordinate processing units (namely, Tex-Gen state and enables, and matrices) will generate an INVALID_OPERATION error if the value of ACTIVE_TEXTURE is greater than or equal to MAX_TEXTURE_COORDS. All other texture state queries will result in an INVALID_OPERATION error if the value of ACTIVE_TEXTURE is greater than or equal to MAX_COMBINED_TEXTURE_IMAGE_UNITS.

Vertex array state variables are qualified by the value of VERTEX_ARRAY_BINDING to determine which vertex array object is queried. Tables 6.7-6.10 define the set of state stored in a vertex array object.

### 6.1.3 Enumerated Queries

Other commands exist to obtain state variables that are identified by a category as well as a symbolic constant.
6.1. QUERYING GL STATE

```c
void GetClipPlane(enum plane, double eqn[4]);
```

returns four double-precision values in `eqn`; these are the coefficients of the plane equation of `plane` in eye coordinates (these coordinates are those that were computed when the plane was specified).

```c
void GetLight(v( enum light, enum value, T data );
```

places information about light parameter `value` for `light` in `data`. `POSITION` and `SPOT_DIRECTION` return values in eye coordinates. Again, these are the coordinates that were computed when the position or direction was specified.

```c
void GetMaterial(v( enum face, enum value, T data );
```

places information about material property `value` for `face` in `data`. `face` must be either `FRONT` or `BACK`, indicating the front or back material, respectively.

```c
void GetTexEnv(v( enum env, enum value, T data );
```

places information about `value` for `env` in `data`. `env` must be either `POINT_SPRITE`, `TEXTURE_ENV`, or `TEXTURE_FILTER_CONTROL`.

```c
void GetTexGen(v( enum coord, enum value, T data );
```

places information about `value` for `coord` in `data`. `coord` must be one of `S`, `T`, `R`, or `Q`. `EYE_LINEAR` coefficients are returned in the eye coordinates that were computed when the plane was specified; `OBJECT_LINEAR` coefficients are returned in object coordinates.

```c
void GetPixelMap(v( enum map, T data );
```

returns all values in the pixel map `map` in `data`. `map` must be a map name from table 3.3. `GetPixelMapui` and `GetPixelMapus` convert floating point pixel map values to integers according to the `UNSIGNED_INT` and `UNSIGNED_SHORT` entries, respectively, of table 4.9.

If a pixel pack buffer is bound (as indicated by a non-zero value of `PIXEL_-PACK_BUFFER_BINDING`), `data` is an offset into the pixel pack buffer; otherwise, `data` is a pointer to client memory. All pixel storage and pixel transfer modes are ignored when returning a pixel map. `n` machine units are written where `n` is the size of the pixel map times the size of `FLOAT`, `UNSIGNED_INT`, or `UNSIGNED_SHORT` respectively in basic machine units. If a pixel pack buffer object is bound and `data + n` is greater than the size of the pixel buffer, an `INVALID_OPERATION` error results. If a pixel pack buffer object is bound and `data` is not evenly divisible by the number of basic machine units needed to store in memory a `FLOAT`, `UNSIGNED_-INT`, or `UNSIGNED_SHORT` respectively, an `INVALID_OPERATION` error results.
6.1. QUERYING GL STATE

```c
void GetMap(ifd) v(enum map, enum value, T data);
```

places information about value for map in data. map must be one of the map types described in section 5.1, and value must be one of ORDER, COEFF, or DOMAIN.

The commands

```c
void GetTexParameter(i) v(enum target, enum value, T data);
void GetTexParameterI( i ui ) v(enum target, enum value, T data);
```

place information about texture parameter value for the specified target into data. value must be TEXTURE_RESIDENT or one of the symbolic values in table 3.22.

`target` may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, TEXTURE_RECTANGLE, or TEXTURE_CUBE_-

Querying value TEXTURE_BORDER_COLOR with GetTexParameterIiv or Get-

TexParameterIuiv returns the border color values as signed integers or unsigned integers, respectively; otherwise the values are returned as described in section 6.1.2. If the border color is queried with a type that does not match the original type with which it was specified, the result is undefined.

```c
void Get TexLevelParameter(i) v( enum target, int lod, enum value, T data);
```

places information about texture image parameter value for level-of-detail lod of the specified target into data. value must be one of the symbolic values in table 6.23.

`target` may be one of TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, TEXTURE_RECTANGLE, TEXTURE_CUBE_-MAP, TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_-MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_-MAP_POSITIVE_Z, TEXTURE_CUBE_MAP_NEGATIVE_Z, TEXTURE_2D_-MULTISAMPLE, TEXTURE_2D_MULTISAMPLE_ARRAY, PROXY_TEXTURE_1D, PROXY_TEXTURE_2D, PROXY_TEXTURE_3D, PROXY_TEXTURE_1D_ARRAY, PROXY_TEXTURE_2D_ARRAY, PROXY_TEXTURE_RECTANGLE, PROXY_-TEXTURE_CUBE_MAP, PROXY_TEXTURE_2D_MULTISAMPLE, or PROXY_-TEXTURE_2D_MULTISAMPLE_ARRAY, indicating the one-, two-, or three-
dimensional texture, one-or two-dimensional array texture, rectangular texture, one of the six distinct 2D images making up the cube map texture object,
two-dimensional multisample texture, two-dimensional multisample array texture; or the one-, two-, three-dimensional, one-or two-dimensional array, rectangular, cube map, two-dimensional multisample, or two-dimensional multisample array proxy state vector.

*target* may also be TEXTURE_BUFFER, indicating the texture buffer. In the case *lod* must be zero or an INVALID_VALUE error is generated.

Note that TEXTURE_CUBE_MAP is not a valid *target* parameter for GetTexLevelParameter, because it does not specify a particular cube map face.

*lod* determines which level-of-detail’s state is returned. If *lod* is less than zero or larger than the maximum allowable level-of-detail, then an INVALID_VALUE error is generated.

For texture images with uncompressed internal formats, queries of *value* TEXTURE_RED_TYPE, TEXTURE_GREEN_TYPE, TEXTURE_BLUE_TYPE, TEXTURE_ALPHA_TYPE, TEXTURE_LUMINANCE_TYPE, TEXTURE_INTENSITY_TYPE, and TEXTURE_DEPTH_TYPE return the data type used to store the component. Types NONE, SIGNED_NORMALIZED, UNSIGNED_NORMALIZED, FLOAT, INT, and UNSIGNED_INT respectively indicate missing, signed normalized fixed-point, unsigned normalized fixed-point, floating-point, signed unnormalized integer, and unsigned unnormalized integer components. Queries of *value* TEXTURE_RED_SIZE, TEXTURE_GREEN_SIZE, TEXTURE_BLUE_SIZE, TEXTURE_ALPHA_SIZE, TEXTURE_LUMINANCE_SIZE, TEXTURE_INTENSITY_SIZE, TEXTURE_DEPTH_SIZE, TEXTURE_STENCIL_SIZE, and TEXTURE_SHARED_SIZE return the actual resolutions of the stored image array components, not the resolutions specified when the image array was defined.

For texture images with compressed internal formats, the types returned specify how components are interpreted after decompression, while the resolutions returned specify the component resolution of an uncompressed internal format that produces an image of roughly the same quality as the compressed image in question. Since the quality of the implementation’s compression algorithm is likely data-dependent, the returned component sizes should be treated only as rough approximations.

Querying *value* TEXTURE_COMPRESSED_IMAGE_SIZE returns the size (in ubyte)s of the compressed texture image that would be returned by GetCompressedTexImage (section 6.1.4). Querying TEXTURE_COMPRESSED_IMAGE_SIZE is not allowed on texture images with an uncompressed internal format or on proxy targets and will result in an INVALID_OPERATION error if attempted.

Queries of *value* TEXTURE_BORDER, TEXTURE_WIDTH, TEXTURE_HEIGHT, and TEXTURE_DEPTH return the border width, width, height, and depth as specified when the image array was created. The internal format of the image array is
6.1. QUERYING GL STATE

queried as TEXTURE_INTERNAL_FORMAT, or as TEXTURE_COMPONENTS for compatibility with GL version 1.0.

6.1.4 Texture Queries

The command

```c
void GetTexImage( enum tex, int lod, enum format,
                   enum type, void *img );
```

is used to obtain texture images. It is somewhat different from the other Get* commands; tex is a symbolic value indicating which texture (or texture face in the case of a cube map texture target name) is to be obtained. TEXTURE_1D, TEXTURE_2D, TEXTURE_3D, TEXTURE_1D_ARRAY, TEXTURE_2D_ARRAY, and TEXTURE_RECTANGLE indicate a one-, two-, or three-dimensional, one- or two-dimensional array, or rectangular texture respectively. TEXTURE_CUBE_MAP_POSITIVE_X, TEXTURE_CUBE_MAP_NEGATIVE_X, TEXTURE_CUBE_MAP_POSITIVE_Y, TEXTURE_CUBE_MAP_NEGATIVE_Y, TEXTURE_CUBE_MAP_POSITIVE_Z, and TEXTURE_CUBE_MAP_NEGATIVE_Z indicate the respective face of a cube map texture. lod is a level-of-detail number, format is a pixel format from table 3.6, type is a pixel type from table 3.5.

Any of the following mismatches between format and the internal format of the texture image will generate an INVALID_OPERATION error:

- format is a color format (one of the formats in table 3.6 whose target is the color buffer) and the base internal format of the texture image is not a color format.
- format is DEPTH_COMPONENT and the base internal format is not DEPTH_-COMPONENT or DEPTH_STENCIL.
- format is DEPTH_STENCIL and the base internal format is not DEPTH_-STENCIL.
- format is one of the integer formats in table 3.6 and the internal format of the texture image is not integer, or format is not one of the integer formats in table 3.6 and the internal format is integer.

GetTexImage obtains component groups from a texture image with the indicated level-of-detail. If format is a color format then the components are assigned among R, G, B, and A according to table 6.1, starting with the first group in the
first row, and continuing by obtaining groups in order from each row and proceeding from the first row to the last, and from the first image to the last for three-dimensional textures. One- and two-dimensional array textures are treated as two- and three-dimensional images, respectively, where the layers are treated as rows or images. If \textit{format} is \texttt{DEPTH\_COMPONENT}, then each depth component is assigned with the same ordering of rows and images. If \textit{format} is \texttt{DEPTH\_STENCIL}, then each depth component and each stencil index is assigned with the same ordering of rows and images.

These groups are then packed and placed in client or pixel buffer object memory. If a pixel pack buffer is bound (as indicated by a non-zero value of \texttt{PIXEL\_PACK\_BUFFER\_BINDING}), \textit{img} is an offset into the pixel pack buffer; otherwise, \textit{img} is a pointer to client memory. No pixel transfer operations are performed on this image, but pixel storage modes that are applicable to \texttt{ReadPixels} are applied.

For three-dimensional and two-dimensional array textures, pixel storage operations are applied as if the image were two-dimensional, except that the additional pixel storage state values \texttt{PACK\_IMAGE\_HEIGHT} and \texttt{PACK\_SKIP\_IMAGES} are applied. The correspondence of texels to memory locations is as defined for \texttt{TexImage3D} in section 3.9.1.

The row length, number of rows, image depth, and number of images are determined by the size of the texture image (including any borders). Calling \texttt{GetTexImage} with \textit{lod} less than zero or larger than the maximum allowable causes the error \texttt{INVALID\_VALUE}. Calling \texttt{GetTexImage} with a \texttt{format} of \texttt{COLOR\_INDEX} or \texttt{STENCIL\_INDEX} causes the error \texttt{INVALID\_ENUM}. Calling \texttt{GetTexImage} with a non-zero \textit{lod} when \textit{tex} is \texttt{TEXTURE\_RECTANGLE} causes the error \texttt{INVALID\_VALUE}. If a pixel pack buffer object is bound and packing the texture image into the buffer’s memory would exceed the size of the buffer, an \texttt{INVALID\_OPERATION} error results. If a pixel pack buffer object is bound and \textit{img} is not evenly divisible by the number of basic machine units needed to store in memory the GL data type corresponding to \texttt{type} (see table 3.5), an \texttt{INVALID\_OPERATION} error results.

The command

\begin{verbatim}
void GetCompressedTexImage( enum target, int lod, 
void *img );
\end{verbatim}

is used to obtain texture images stored in compressed form. The parameters \texttt{target}, \texttt{lod}, and \texttt{img} are interpreted in the same manner as in \texttt{GetTexImage}. When called, \texttt{GetCompressedTexImage} writes \(n\) \texttt{ubyte}s of compressed image data to the pixel pack buffer or client memory pointed to by \textit{img}, where \(n\) is the value of \texttt{TEXTURE\_COMPRESSED\_IMAGE\_SIZE} for the texture. The compressed image data is formatted according to the definition of the texture’s internal format. All
6.1. QUERYING GL STATE

</tr>
</tbody>
</table>

Table 6.1: Texture, table, and filter return values. $R_i$, $G_i$, $B_i$, $A_i$, $L_i$, and $I_i$ are components of the internal format that are assigned to pixel values R, G, B, and A. If a requested pixel value is not present in the internal format, the specified constant value is used.

Pixel storage and pixel transfer modes are ignored when returning a compressed texture image.

Calling `GetCompressedTexImage` with an `lod` value less than zero or greater than the maximum allowable causes an `INVALID_VALUE` error. Calling `GetCompressedTexImage` with a texture image stored with an uncompressed internal format causes an `INVALID_OPERATION` error. If a pixel pack buffer object is bound and $img + n$ is greater than the size of the buffer, an `INVALID_OPERATION` error results.

The command

```c
boolean IsTexture( uint texture );
```

returns `TRUE` if `texture` is the name of a texture object. If `texture` is zero, or is a non-zero value that is not the name of a texture object, or if an error condition occurs, `IsTexture` returns `FALSE`. A name returned by `GenTextures`, but not yet bound, is not the name of a texture object.

6.1.5 Stipple Query

The command

```c
void GetPolygonStipple( void *pattern );
```

obtains the polygon stipple. The pattern is packed into pixel pack buffer or client memory according to the procedure given in section 4.3.2 for `ReadPixels`; it is as

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
if the height and width passed to that command were both equal to 32, the type were BITMAP, and the format were COLOR_INDEX.

6.1.6 Color Matrix Query

The scale and bias variables are queried using `GetFloatv` with `pname` set to the appropriate variable name. The top matrix on the color matrix stack is returned by `GetFloatv` called with `pname` set to COLOR_MATRIX or TRANSPOSE_COLOR_MATRIX. The depth of the color matrix stack, and the maximum depth of the color matrix stack, are queried with `GetIntegerv`, setting `pname` to COLOR_MATRIX_STACK_DEPTH and MAX_COLOR_MATRIX_STACK_DEPTH respectively.

6.1.7 Color Table Query

The current contents of a color table are queried using

```c
void GetColorTable( enum target, enum format, enum type,
                    void *table );
```

target must be one of the regular color table names listed in table 3.4. format and type accept the same values as do the corresponding parameters of `GetTexImage`, except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM. The one-dimensional color table image is returned to pixel pack buffer or client memory starting at `table`. No pixel transfer operations are performed on this image, but pixel storage modes that are applicable to `ReadPixels` are performed. Color components that are requested in the specified format, but which are not included in the internal format of the color lookup table, are returned as zero. The assignments of internal color components to the components requested by `format` are described in table 6.1.

The functions

```c
void GetColorTableParameter{if}v( enum target,
                                enum pname, T params );
```

are used for integer and floating point query.

target must be one of the regular or proxy color table names listed in table 3.4. `pname` is one of COLOR_TABLE_SCALE, COLOR_TABLE_BIAS, COLOR_TABLE_FORMAT, COLOR_TABLE_WIDTH, COLOR_TABLE_RED_SIZE, COLOR_TABLE_GREEN_SIZE, COLOR_TABLE_BLUE_SIZE, COLOR_TABLE_ALPHA_SIZE, COLOR_TABLE_LUMINANCE_SIZE, or COLOR_TABLE_INTENSITY_SIZE. The value of the specified parameter is returned in `params`. 

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
6.1.8 Convolution Query

The current contents of a convolution filter image are queried with the command

```c
void GetConvolutionFilter( enum target, enum format,
                         enum type, void *image );
```

target must be CONVOLUTION_1D or CONVOLUTION_2D. format and type accept the same values as do the corresponding parameters of GetTexImage, except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM. The one-dimensional or two-dimensional images is returned to pixel pack buffer or client memory starting at image. Pixel processing and component mapping are identical to those of GetTexImage.

The current contents of a separable filter image are queried using

```c
void GetSeparableFilter( enum target, enum format,
                        enum type, void *row, void *column, void *span );
```

target must be SEPARABLE_2D. format and type accept the same values as do the corresponding parameters of GetTexImage. The row and column images are returned to pixel pack buffer or client memory starting at row and column respectively. span is currently unused. Pixel processing and component mapping are identical to those of GetTexImage.

The functions

```c
void GetConvolutionParameter( enum target,
                              enum pname, T params );
```

are used for integer and floating point query. target must be CONVOLUTION_1D, CONVOLUTION_2D, or SEPARABLE_2D. pname is one of CONVOLUTION_BORDER_COLOR, CONVOLUTION_BORDER_MODE, CONVOLUTION_FILTER_SCALE, CONVOLUTION_FILTER_BIAS, CONVOLUTION_FORMAT, CONVOLUTION_WIDTH, CONVOLUTION_HEIGHT, MAX_CONVOLUTION_WIDTH, or MAX_CONVOLUTION_HEIGHT. The value of the specified parameter is returned in params.

6.1.9 Histogram Query

The current contents of the histogram table are queried using

```c
void GetHistogram( enum target, boolean reset,
                   enum format, enum type, void *values );
```
target must be HISTOGRAM. format and type accept the same values as do the corresponding parameters of GetTexImage, except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM. The one-dimensional histogram table image is returned to pixel pack buffer or client memory starting at values. Pixel processing and component mapping are identical to those of GetTexImage, except that instead of applying the Final Conversion pixel storage mode, component values are simply clamped to the range of the target data type.

If reset is TRUE, then all counters of all elements of the histogram are reset to zero. Counters are reset whether returned or not.

No counters are modified if reset is FALSE.

Calling

```c
void ResetHistogram( enum target );
```

resets all counters of all elements of the histogram table to zero. target must be HISTOGRAM.

It is not an error to reset or query the contents of a histogram table with zero entries.

The functions

```c
void GetHistogramParameter( enum target,
    enum pname, T params );
```

are used for integer and floating point query. target must be HISTOGRAM or PROXY_HISTOGRAM. pname is one of HISTOGRAM_FORMAT, HISTOGRAM_WIDTH, HISTOGRAM_RED_SIZE, HISTOGRAM_GREEN_SIZE, HISTOGRAM_BLUE_SIZE, HISTOGRAM_ALPHA_SIZE, or HISTOGRAM_LUMINANCE_SIZE. pname may be HISTOGRAM_SINK only for target HISTOGRAM. The value of the specified parameter is returned in params.

6.1.10 Minmax Query

The current contents of the minmax table are queried using

```c
void GetMinmax( enum target, boolean reset, enum format,
    enum type, void* values );
```

target must be MINMAX. format and type accept the same values as do the corresponding parameters of GetTexImage, except that a format of DEPTH_COMPONENT causes the error INVALID_ENUM. A one-dimensional image of width 2 is returned.
6.1. QUERYING GL STATE

to pixel pack buffer or client memory starting at values. Pixel processing and com-
ponent mapping are identical to those of GetTexImage.

If reset is TRUE, then each minimum value is reset to the maximum represent-
able value, and each maximum value is reset to the minimum representable
value. All values are reset, whether returned or not.

No values are modified if reset is FALSE.

Calling

    void ResetMinmax(enum target);

resets all minimum and maximum values of target to to their maximum and mini-
mum representable values, respectively, target must be MINMAX.

The functions

    void GetMinmaxParameter{if}v(enum target, enum pname,
                             T params);

are used for integer and floating point query. target must be MINMAX. pname is
MINMAX_FORMAT or MINMAX_SINK. The value of the specified parameter is re-
turned in params.

6.1.11 Pointer and String Queries

The command

    void GetPointerv(enum pname, void **params);

obtains the pointer or pointers named pname in the array params. The possible values for pname are SELECTION_BUFFER_POINTER and FEEDBACK-
BUFFER_POINTER, which respectively return the pointers set with SelectBuffer
and FeedbackBuffer; and VERTEX_ARRAY_POINTER, NORMAL_ARRAY_-POINTER, COLOR_ARRAY_POINTER, SECONDARY_COLOR_ARRAY_POINTER,
INDEX_ARRAY_POINTER, TEXTURE_COORD_ARRAY_POINTER, FOG_COORD_-ARRAY_POINTER, and EDGE_FLAG_ARRAY_POINTER, which respectively return
the corresponding value stored in the currently bound vertex array object. Each
pname returns a single pointer value.

String queries return pointers to UTF-8 encoded, NULL-terminated static strings describing properties of the current GL context.

1 Applications making copies of these static strings should never use a fixed-length buffer, because the strings may grow unpredictably between releases, resulting in buffer overflow when copying. This is particularly true of the EXTENSIONS string, which has become extremely long in some GL implementations.
6.1. QUERYING GL STATE

<table>
<thead>
<tr>
<th>Value</th>
<th>OpenGL Profile</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTEXT_CORE_PROFILE_BIT</td>
<td>Core</td>
</tr>
<tr>
<td>CONTEXT_COMPATIBILITY_PROFILE_BIT</td>
<td>Compatibility</td>
</tr>
</tbody>
</table>

Table 6.2: Context profile bits returned by the CONTEXT_PROFILE_MASK query.

ubyte *GetString( enum name );

accepts name values of RENDERER, VENDOR, EXTENSIONS, VERSION, and SHADING_LANGUAGE_VERSION. The format of the RENDERER and VENDOR strings is implementation-dependent. The EXTENSIONS string contains a space separated list of extension names (the extension names themselves do not contain any spaces). The VERSION and SHADING_LANGUAGE_VERSION strings are laid out as follows:

<version number><space><vendor-specific information>

The version number is either of the form major_number.minor_number or major_number.minor_number.release_number, where the numbers all have one or more digits. The release_number and vendor specific information are optional. However, if present, then they pertain to the server and their format and contents are implementation-dependent.

GetString returns the version number (in the VERSION string) and the extension names (in the EXTENSIONS string) that can be supported by the current GL context. Thus, if the client and server support different versions and/or extensions, a compatible version and list of extensions is returned.

The version, profile, and additional properties of the context may also be queried by calling GetInteger with values MAJOR_VERSION and MINOR_VERSION, which respectively return the same values as major_number and minor_number in the VERSION string; with value CONTEXT_PROFILE_MASK, which returns a mask containing one of the bits in table 6.2, corresponding to the API profile implemented by the context (see appendix E.1); or with value CONTEXT_FLAGS, which returns a set of flags defining additional properties of a context.

If CONTEXT_FLAG_FORWARD_COMPATIBLE_BIT is set in CONTEXT_FLAGS, then the context is a forward-compatible context as defined in appendix E, and the deprecated features described in that appendix are not supported; otherwise the context is a full context, and all features described in the specification are supported.

Indexed strings are queried with the command

ubyte *GetStringi( enum name, uint index );
6.1. QUERYING GL STATE

name is the name of the indexed state and index is the index of the particular element being queried. name may only be EXTENSIONS, indicating that the extension name corresponding to the index'th supported extension should be returned. index may range from zero to the value of NUM_EXTENSIONS minus one. All extension names, and only the extension names returned in GetString(EXTENSIONS) will be returned as individual names, but there is no defined relationship between the order in which names appear in the non-indexed string and the order in which they appear in the indexed query. There is no defined relationship between any particular extension name and the index values; an extension name may correspond to a different index in different GL contexts and/or implementations.

An INVALID_VALUE error is generated if index is outside the valid range for the indexed state name.

6.1.12 Asynchronous Queries

The command

    boolean IsQuery( uint id );

returns TRUE if id is the name of a query object. If id is zero, or if id is a non-zero value that is not the name of a query object, IsQuery returns FALSE.

Information about a query target can be queried with the command

    void GetQueryiv( enum target, enum pname, int *params );

target identifies the query target, and must be one of SAMPLES_PASSED for occlusion queries or PRIMITIVES_GENERATED and TRANSFORM_FEEDBACK_PRIMITIVES_WRITTEN for primitive queries. If pname is CURRENT_QUERY, the name of the currently active query for target, or zero if no query is active, will be placed in params.

If pname is QUERY_COUNTER_BITS, the implementation-dependent number of bits used to hold the query result for target will be placed in params. The number of query counter bits may be zero, in which case the counter contains no useful information.

For primitive queries (PRIMITIVES_GENERATED and TRANSFORM_FEEDBACK_PRIMITIVES_WRITTEN) if the number of bits is non-zero, the minimum number of bits allowed is 32.

For occlusion queries (SAMPLES_PASSED), if the number of bits is non-zero, the minimum number of bits allowed is a function of the implementation’s maximum viewport dimensions (MAX_VIEWPORT_DIMS). The counter must be able to represent at least two overdraws for every pixel in the viewport. The formula to

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
compute the allowable minimum value (where $n$ is the minimum number of bits) is

$$n = \min\{32, \lceil \log_2(maxViewportWidth \times maxViewportHeight \times 2) \rceil \}.$$ 

The state of a query object can be queried with the commands

```c
void GetQueryObjectiv(uint id, enum pname, int *params);
void GetQueryObjectuiv(uint id, enum pname, uint *params);
```

If $id$ is not the name of a query object, or if the query object named by $id$ is currently active, then an INVALID_OPERATION error is generated.

If $pname$ is QUERY_RESULT, then the query object’s result value is returned as a single integer in $params$. If the value is so large in magnitude that it cannot be represented with the requested type, then the nearest value representable using the requested type is returned. If the number of query counter bits for $target$ is zero, then the result is returned as a single integer with the value zero.

There may be an indeterminate delay before the above query returns. If $pname$ is QUERY_RESULT_AVAILABLE, FALSE is returned if such a delay would be required; otherwise TRUE is returned. It must always be true that if any query object returns a result available of TRUE, all queries of the same type issued prior to that query must also return TRUE.

Querying the state for any given query object forces that occlusion query to complete within a finite amount of time.

If multiple queries are issued using the same object name prior to calling GetQueryObject[ui]v, the result and availability information returned will always be from the last query issued. The results from any queries before the last one will be lost if they are not retrieved before starting a new query on the same $target$ and $id$.

### 6.1.13 Sync Object Queries

Properties of sync objects may be queried using the command

```c
void GetSynciv(sync sync, enum pname, sizei bufSize, sizei *length, int *values);
```

The value or values being queried are returned in the parameters $length$ and $values$.
6.1. QUERYING GL STATE

On success, GetSynciv replaces up to bufSize integers in values with the corresponding property values of the object being queried. The actual number of integers replaced is returned in *length. If length is NULL, no length is returned.

If pname is OBJECT_TYPE, a single value representing the specific type of the sync object is placed in values. The only type supported is SYNC_FENCE.

If pname is SYNC_STATUS, a single value representing the status of the sync object (SIGNALED or UNSIGNALED) is placed in values.

If pname is SYNC_CONDITION, a single value representing the condition of the sync object is placed in values. The only condition supported is SYNC_GPU_COMMANDS_COMPLETE.

If pname is SYNC_FLAGS, a single value representing the flags with which the sync object was created is placed in values. No flags are currently supported.

If sync is not the name of a sync object, an INVALID_VALUE error is generated. If pname is not one of the values described above, an INVALID_ENUM error is generated. If an error occurs, nothing will be written to values or length.

The command

    boolean IsSync( sync sync );

returns TRUE if sync is the name of a sync object. If sync is not the name of a sync object, or if an error condition occurs, IsSync returns FALSE (note that zero is not the name of a sync object).

Sync object names immediately become invalid after calling DeleteSync, as discussed in sections 5.6 and D.2, but the underlying sync object will not be deleted until it is no longer associated with any fence command and no longer blocking any *WaitSync command.

6.1.14 Buffer Object Queries

The command

    boolean IsBuffer( uint buffer );

returns TRUE if buffer is the name of an buffer object. If buffer is zero, or if buffer is a non-zero value that is not the name of an buffer object, IsBuffer returns FALSE.

The commands

    void GetBufferParameteriv( enum target, enum pname, int *data );
    void GetBufferParameteri64v( enum target, enum pname, int64 *data );
6.1. QUERYING GL STATE

return information about a bound buffer object. target must be one of the targets listed in table 2.7, and pname must be one of the buffer object parameters in table 2.8, other than BUFFER_MAP_POINTER. The value of the specified parameter of the buffer object bound to target is returned in data.

The command

```
void GetBufferSubData( enum target, intptr offset, sizeiptr size, void *data );
```

queries the data contents of a buffer object. target must be one of the targets listed in table 2.7. offset and size indicate the range of data in the buffer object that is to be queried, in terms of basic machine units. data specifies a region of client memory, size basic machine units in length, into which the data is to be retrieved.

An error is generated if GetBufferSubData is executed for a buffer object that is currently mapped.

While the data store of a buffer object is mapped, the pointer to the data store can be queried by calling

```
void GetBufferPointerv( enum target, enum pname, void **params );
```

with target set to one of the targets listed in table 2.7 and pname set to BUFFER_-MAP_POINTER. The single buffer map pointer is returned in params. GetBufferPointerv returns the NULL pointer value if the buffer’s data store is not currently mapped, or if the requesting client did not map the buffer object’s data store, and the implementation is unable to support mappings on multiple clients.

To query which buffer objects are bound to the array of uniform buffer binding points and will be used as the storage for active uniform blocks, call GetIntegeri_v with param set to UNIFORM_BUFFER_BINDING. index must be in the range zero to the value of MAX_UNIFORM_BUFFER_BINDINGS - 1. The name of the buffer object bound to index is returned in values. If no buffer object is bound for index, zero is returned in values.

To query the starting offset or size of the range of each buffer object binding used for uniform buffers, call GetInteger64i_v with param set to UNIFORM_-BUFFER_START or UNIFORM_Buffer_SIZE respectively. index must be in the range zero to the value of MAX_UNIFORM_BUFFER_BINDINGS - 1. If the parameter (starting offset or size) was not specified when the buffer object was bound, zero is returned. If no buffer object is bound to index, -1 is returned.

To query which buffer objects are bound to the array of transform feedback binding points and will be used when transform feedback is active, call GetIntegeri_v with param set to TRANSFORM_FEEDBACK_BUFFER_BINDING. index must
be in the range zero to the value of MAX_TRANSFORM_FEEDBACK_SEPARATE_ATTRIBS - 1. The name of the buffer object bound to index is returned in values. If no buffer object is bound for index, zero is returned in values.

To query the starting offset or size of the range of each buffer object binding used for transform feedback, call GetInteger64iv with param set to TRANSFORM_FEEDBACK_BUFFER_START or TRANSFORM_FEEDBACK_BUFFER_SIZE respectively. index must be in the range 0 to the value of MAX_TRANSFORM_FEEDBACK_SEPARATE_ATTRIBS - 1. If the parameter (starting offset or size) was not specified when the buffer object was bound, zero is returned. If no buffer object is bound to index, -1 is returned.

6.1.15 Vertex Array Object Queries

The command

boolean IsVertexArray( uint array );

returns TRUE if array is the name of a vertex array object. If array is zero, or a non-zero value that is not the name of a vertex array object, IsVertexArray returns FALSE. No error is generated if array is not a valid vertex array object name.

6.1.16 Shader and Program Queries

State stored in shader or program objects can be queried by commands that accept shader or program object names. These commands will generate the error INVALID_VALUE if the provided name is not the name of either a shader or program object, and INVALID_OPERATION if the provided name identifies an object of the other type. If an error is generated, variables used to hold return values are not modified.

The command

boolean IsShader( uint shader );

returns TRUE if shader is the name of a shader object. If shader is zero, or a non-zero value that is not the name of a shader object, IsShader returns FALSE. No error is generated if shader is not a valid shader object name.

The command

void GetShaderiv( uint shader, enum pname, int *params );
6.1. QUERYING GL STATE

returns properties of the shader object named shader in params. The parameter value to return is specified by pname.

If pname is SHADER_TYPE, VERTEX_SHADER, GEOMETRY_SHADER, or FRAGMENT_SHADER is returned if shader is a vertex, geometry, or fragment shader object respectively. If pname is DELETE_STATUS, TRUE is returned if the shader has been flagged for deletion and FALSE is returned otherwise. If pname is COMPILATION_STATUS, TRUE is returned if the shader was last compiled successfully, and FALSE is returned otherwise. If pname is INFO_LOG_LENGTH, the length of the info log, including a null terminator, is returned. If there is no info log, zero is returned. If pname is SHADER_SOURCE_LENGTH, the length of the concatenation of the source strings making up the shader source, including a null terminator, is returned. If no source has been defined, zero is returned.

The command

    boolean IsProgram( uint program );

returns TRUE if program is the name of a program object. If program is zero, or a non-zero value that is not the name of a program object, IsProgram returns FALSE. No error is generated if program is not a valid program object name.

The command

    void GetProgramiv( uint program, enum pname, int *params );

returns properties of the program object named program in params. The parameter value to return is specified by pname.

If pname is DELETE_STATUS, TRUE is returned if the program has been flagged for deletion, and FALSE is returned otherwise. If pname is LINK_STATUS, TRUE is returned if the program was last compiled successfully, and FALSE is returned otherwise. If pname is VALIDATE_STATUS, TRUE is returned if the last call to ValidateProgram with program was successful, and FALSE is returned otherwise. If pname is INFO_LOG_LENGTH, the length of the info log, including a null terminator, is returned. If there is no info log, zero is returned. If pname is ATTACHED_SHADERS, the number of objects attached is returned. If pname is ACTIVE_ATTRIBUTES, the number of active attributes in program is returned. If no active attributes exist, zero is returned. If pname is ACTIVE_ATTRIBUTE_MAX_LENGTH, the length of the longest active attribute name, including a null terminator, is returned. If no active attributes exist, zero is returned. If pname is ACTIVE_UNIFORMS, the number of active uniforms is returned. If no active uniforms exist, zero is returned. If pname is ACTIVE_UNIFORM_MAX_LENGTH, the length of
the longest active uniform name, including a null terminator, is returned. If no active uniforms exist, zero is returned. If \( \text{pname} \) is \text{TRANSFORM_FEEDBACK_BUFFER_MODE}, the buffer mode used when transform feedback is active is returned. It can be one of \text{SEPARATE_ATTRIBS} or \text{INTERLEAVED_ATTRIBS}. If \( \text{pname} \) is \text{TRANSFORM_FEEDBACK_VARYINGS}, the number of varying variables to capture in transform feedback mode for the program is returned. If \( \text{pname} \) is \text{TRANSFORM_FEEDBACK_VARYING_MAX_LENGTH}, the length of the longest varying name specified to be used for transform feedback, including a null terminator, is returned. If no varyings are used for transform feedback, zero is returned. If \( \text{pname} \) is \text{TRANSFORM_FEEDBACK_VARYING_MAX_LENGTH}, the length of the longest varying name specified to be used for transform feedback, including a null terminator, is returned. If no varyings are used for transform feedback, zero is returned. If \( \text{pname} \) is \text{ACTIVE_UNIFORM_BLOCKS}, the number of uniform blocks for program containing active uniforms is returned. If \( \text{pname} \) is \text{ACTIVE_UNIFORM_BLOCK_MAX_NAME_LENGTH}, the length of the longest active uniform block name, including the null terminator, is returned. If \( \text{pname} \) is \text{GEOMETRY_VERTICES_OUT}, the maximum number of vertices the geometry shader will output is returned. If \( \text{pname} \) is \text{GEOMETRY_INPUT_TYPE}, the geometry shader input type, which must be one of \text{POINTS}, \text{LINES}, \text{LINES_ADJACENCY}, \text{TRIANGLES} or \text{TRIANGLES_ADJACENCY}, is returned. If \( \text{pname} \) is \text{GEOMETRY_OUTPUT_TYPE}, the geometry shader output type, which must be one of \text{POINTS}, \text{LINE_STRIP} or \text{TRIANGLE_STRIP}, is returned. If \( \text{GEOMETRY_VERTICES_OUT}, \text{GEOMETRY_INPUT_TYPE}, \) or \text{GEOMETRY_OUTPUT_TYPE} are queried for a program which has not been linked successfully, or which does not contain objects to form a geometry shader, then an \text{INVALID_OPERATION} error is generated.

The command

```c
void GetAttachedShaders( uint program, sizei maxCount,
                        sizei *count, uint *shaders );
```

returns the names of shader objects attached to \text{program} in \text{shaders}. The actual number of shader names written into \text{shaders} is returned in \text{count}. If no shaders are attached, \text{count} is set to zero. If \text{count} is \text{NULL} then it is ignored. The maximum number of shader names that may be written into \text{shaders} is specified by \text{maxCount}. The number of objects attached to \text{program} is given by can be queried by calling \text{GetProgramiv} with \text{ATTACHED_SHADERS}.

A string that contains information about the last compilation attempt on a shader object or last link or validation attempt on a program object, called the \text{info log}, can be obtained with the commands

```c
void GetShaderInfoLog( uint shader, sizei bufSize,
                        sizei *length, char *infoLog );
void GetProgramInfoLog( uint program, sizei bufSize,
                        sizei *length, char *infoLog );
```

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
These commands return the info log string in `infoLog`. This string will be null-terminated. The actual number of characters written into `infoLog`, excluding the null terminator, is returned in `length`. If `length` is `NULL`, then no length is returned. The maximum number of characters that may be written into `infoLog`, including the null terminator, is specified by `bufSize`. The number of characters in the info log can be queried with `GetShaderiv` or `GetProgramiv` with `INFO_LOG_LENGTH`. If `shader` is a shader object, the returned info log will either be an empty string or it will contain information about the last compilation attempt for that object. If `program` is a program object, the returned info log will either be an empty string or it will contain information about the last link attempt or last validation attempt for that object.

The info log is typically only useful during application development and an application should not expect different GL implementations to produce identical info logs.

The command

```c
void GetShaderSource( uint shader, sizei bufSize, 
                    sizei *length, char *source );
```

returns in `source` the string making up the source code for the shader object `shader`. The string `source` will be null-terminated. The actual number of characters written into `source`, excluding the null terminator, is returned in `length`. If `length` is `NULL`, no length is returned. The maximum number of characters that may be written into `source`, including the null terminator, is specified by `bufSize`. The string `source` is a concatenation of the strings passed to the GL using `ShaderSource`. The length of this concatenation is given by `SHADER_SOURCE_LENGTH`, which can be queried with `GetShaderiv`.

The commands

```c
void GetVertexAttribdv( uint index, enum pname, 
                        double *params );
void GetVertexAttribfv( uint index, enum pname, 
                        float *params );
void GetVertexAttribiv( uint index, enum pname, 
                        int *params );
void GetVertexAttribIiv( uint index, enum pname, 
                         int *params );
void GetVertexAttribIuiv( uint index, enum pname, 
                         uint *params );
```
obtain the vertex attribute state named by \textit{pname} for the generic vertex attribute numbered \textit{index} and places the information in the array \textit{params}. \textit{pname} must be one of \texttt{VERTEX_ATTRIB_ARRAY_BUFFER_BINDING}, \texttt{VERTEX_ATTRIB_ARRAY_ENABLED}, \texttt{VERTEX_ATTRIB_ARRAY_SIZE}, \texttt{VERTEX_ATTRIB_ARRAY_STRIDE}, \texttt{VERTEX_ATTRIB_ARRAY_TYPE}, \texttt{VERTEX_ATTRIB_ARRAY_NORMALIZED}, \texttt{VERTEX_ATTRIB_ARRAY_INTEGER}, or \texttt{CURRENT_VERTEX_ATTRIB}. Note that all the queries except \texttt{CURRENT_VERTEX_ATTRIB} return values stored in the currently bound vertex array object (the value of \texttt{VERTEX_ARRAY_BINDING}). If the zero object is bound, these values are client state. The error \texttt{INVALID_VALUE} is generated if \textit{index} is greater than or equal to \texttt{MAX_VERTEX_ATTRIBS}.

All but \texttt{CURRENT_VERTEX_ATTRIB} return information about generic vertex attribute arrays. The enable state of a generic vertex attribute array is set by the command \texttt{EnableVertexAttribArray} and cleared by \texttt{DisableVertexAttribArray}. The size, stride, type, normalized flag, and unconverted integer flag are set by the commands \texttt{VertexAttribPointer} and \texttt{VertexAttribIPointer}. The normalized flag is always set to \texttt{FALSE} by \texttt{VertexAttribIPointer}. The unconverted integer flag is always set to \texttt{FALSE} by \texttt{VertexAttribPointer} and \texttt{TRUE} by \texttt{VertexAttribIPointer}.

The query \texttt{CURRENT_VERTEX_ATTRIB} returns the current value for the generic attribute \textit{index}. \texttt{GetVertexAttribdv} and \texttt{GetVertexAttribfv} read and return the current attribute values as floating-point values; \texttt{GetVertexAttribiv} reads them as floating-point values and converts them to integer values; \texttt{GetVertexAttribIiv} reads and returns them as integers; \texttt{GetVertexAttribIuiv} reads and returns them as unsigned integers. The results of the query are undefined if the current attribute values are read using one data type but were specified using a different one.

The command

\begin{verbatim}
void GetVertexAttribPointerv( uint index, enum pname, 
    void **pointer );
\end{verbatim}

obtains the pointer named \textit{pname} for the vertex attribute numbered \textit{index} and places the information in the array \textit{pointer}. \textit{pname} must be \texttt{VERTEX_ATTRIB_ARRAY_POINTER}. The value returned is queried from the currently bound vertex array object. If the zero object is bound, the value is queried from client state. An \texttt{INVALID_VALUE} error is generated if \textit{index} is greater than or equal to the value of \texttt{MAX_VERTEX_ATTRIBS}.

The commands

\begin{verbatim}
void GetUniformfv( uint program, int location, 
    float *params );
\end{verbatim}
6.1. QUERYING GL STATE

```c
void GetUniformiv(uint program, int location, int *params);
void GetUniformuiv(uint program, int location, uint *params);
```

return the value or values of the uniform at location location of the default uniform block for program object program in the array params. The type of the uniform at location determines the number of values returned. The error INVALID_OPERATION is generated if program has not been linked successfully, or if location is not a valid location for program. In order to query the values of an array of uniforms, a GetUniform* command needs to be issued for each array element. If the uniform queried is a matrix, the values of the matrix are returned in column major order. If an error occurred, params will not be modified.

6.1.17 Framebuffer Object Queries

The command

```c
boolean IsFramebuffer(uint framebuffer);
```

returns TRUE if framebuffer is the name of an framebuffer object. If framebuffer is zero, or if framebuffer is a non-zero value that is not the name of an framebuffer object, IsFramebuffer return FALSE.

The command

```c
void GetFramebufferAttachmentParameteriv(enum target, enum attachment, enum pname, int *params);
```

returns information about attachments of a bound framebuffer object. target must be DRAW_FRAMEBUFFER, READ_FRAMEBUFFER, or FRAMEBUFFER. FRAMEBUFFER is equivalent to DRAW_FRAMEBUFFER.

If the default framebuffer is bound to target, then attachment must be one of FRONT_LEFT, FRONT_RIGHT, BACK_LEFT, BACK_RIGHT, or AUX, identifying a color buffer; DEPTH, identifying the depth buffer; or STENCIL, identifying the stencil buffer.

If a framebuffer object is bound to target, then attachment must be one of the attachment points of the framebuffer listed in table 4.12.

If attachment is DEPTH_STENCIL_ATTACHMENT, and different objects are bound to the depth and stencil attachment points of target, the query will fail and generate an INVALID_OPERATION error. If the same object is bound to both attachment points, information about that object will be returned.
Upon successful return from \texttt{GetFramebufferAttachmentParameteriv}, if \texttt{pname} is \texttt{FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE}, then \texttt{param} will contain one of \texttt{NONE}, \texttt{FRAMEBUFFER_DEFAULT}, \texttt{TEXTURE}, or \texttt{RENDERBUFFER}, identifying the type of object which contains the attached image. Other values accepted for \texttt{pname} depend on the type of object, as described below.

If the value of \texttt{FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE} is \texttt{NONE}, no framebuffer is bound to \texttt{target}. In this case querying \texttt{pname} \texttt{FRAMEBUFFER_ATTACHMENT_OBJECT_NAME} will return zero, and all other queries will generate an \texttt{INVALID_OPERATION} error.

If the value of \texttt{FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE} is not \texttt{NONE}, these queries apply to all other framebuffer types:

- If \texttt{pname} is \texttt{FRAMEBUFFER_ATTACHMENT_RED_SIZE}, \texttt{FRAMEBUFFER_ATTACHMENT_GREEN_SIZE}, \texttt{FRAMEBUFFER_ATTACHMENT_BLUE_SIZE}, \texttt{FRAMEBUFFER_ATTACHMENT_ALPHA_SIZE}, \texttt{FRAMEBUFFER_ATTACHMENT_DEPTH_SIZE}, or \texttt{FRAMEBUFFER_ATTACHMENT_STENCIL_SIZE}, then \texttt{param} will contain the number of bits in the corresponding red, green, blue, alpha, depth, or stencil component of the specified attachment. Zero is returned if the requested component is not present in \texttt{attachment}.

- If \texttt{pname} is \texttt{FRAMEBUFFER_ATTACHMENT_COMPONENT_TYPE}, \texttt{param} will contain the format of components of the specified attachment, one of \texttt{FLOAT}, \texttt{INDEX}, \texttt{INT}, \texttt{UNSIGNED_INT}, \texttt{SIGNED_NORMALIZED}, or \texttt{UNSIGNED_NORMALIZED} for floating-point, index, signed integer, unsigned integer, signed normalized fixed-point, or unsigned normalized fixed-point components respectively. Only color buffers may have index or integer components.

- If \texttt{pname} is \texttt{FRAMEBUFFER_ATTACHMENT_COLOR_ENCODING}, \texttt{param} will contain the encoding of components of the specified attachment, one of \texttt{LINEAR} or \texttt{SRGB} for linear or sRGB-encoded components, respectively. Only color buffer components may be sRGB-encoded; such components are treated as described in sections 4.1.8 and 4.1.9. For the default framebuffer, color encoding is determined by the implementation. For framebuffer objects, components are sRGB-encoded if the internal format of a color attachment is one of the color-renderable SRGB formats described in section 3.9.17.

If the value of \texttt{FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE} is \texttt{RENDERBUFFER}, then
6.1. QUERYING GL STATE

- If `pname` is `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME`, `params` will contain the name of the renderbuffer object which contains the attached image.

If the value of `FRAMEBUFFER_ATTACHMENT_OBJECT_TYPE` is `TEXTURE`, then

- If `pname` is `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME`, then `params` will contain the name of the texture object which contains the attached image.

- If `pname` is `FRAMEBUFFER_ATTACHMENT_TEXTURE_LEVEL`, then `params` will contain the mipmap level of the texture object which contains the attached image.

- If `pname` is `FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE` and the texture object named `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME` is a cube map texture, then `params` will contain the cube map face of the cube-map texture object which contains the attached image. Otherwise `params` will contain the value zero.

- If `pname` is `FRAMEBUFFER_ATTACHMENT_TEXTURE_LAYER` and the texture object named `FRAMEBUFFER_ATTACHMENT_OBJECT_NAME` is a layer of a three-dimensional texture or a one-or two-dimensional array texture, then `params` will contain the number of the texture layer which contains the attached image. Otherwise `params` will contain the value zero.

- If `pname` is `FRAMEBUFFER_ATTACHMENT_LAYERED`, then `params` will contain `TRUE` if an entire level of a three-dimensional texture, cube map texture, or one-or two-dimensional array texture is attached. Otherwise, `params` will contain `FALSE`.

Any combinations of framebuffer type and `pname` not described above will generate an `INVALID_ENUM` error.

6.1.18 Renderbuffer Object Queries

The command

```python
boolean IsRenderbuffer ( uint renderbuffer );
```

returns `TRUE` if `renderbuffer` is the name of a renderbuffer object. If `renderbuffer` is zero, or if `renderbuffer` is a non-zero value that is not the name of a renderbuffer object, `IsRenderbuffer` return `FALSE`.

The command
6.1. QUERYING GL STATE

```c
void GetRenderbufferParameteriv( enum target, enum pname, int* params );
```

returns information about a bound renderbuffer object. `target` must be `RENDERBUFFER` and `pname` must be one of the symbolic values in table 6.33. If the renderbuffer currently bound to `target` is zero, then an `INVALID_OPERATION` error is generated.

Upon successful return from `GetRenderbufferParameteriv`, if `pname` is `RENDERBUFFER_WIDTH`, `RENDERBUFFER_HEIGHT`, `RENDERBUFFER_INTERNAL_FORMAT`, or `RENDERBUFFER_SAMPLES`, then `params` will contain the width in pixels, height in pixels, internal format, or number of samples, respectively, of the image of the renderbuffer currently bound to `target`.

If `pname` is `RENDERBUFFER_RED_SIZE`, `RENDERBUFFER_GREEN_SIZE`, `RENDERBUFFER_BLUE_SIZE`, `RENDERBUFFER_ALPHA_SIZE`, `RENDERBUFFER_DEPTH_SIZE`, or `RENDERBUFFER_STENCIL_SIZE`, then `params` will contain the actual resolutions (not the resolutions specified when the image array was defined) for the red, green, blue, alpha depth, or stencil components, respectively, of the image of the renderbuffer currently bound to `target`.

Otherwise, an `INVALID_ENUM` error is generated.

6.1.19 Saving and Restoring State

Besides providing a means to obtain the values of state variables, the GL also provides a means to save and restore groups of state variables. The `PushAttrib`, `PushClientAttrib`, `PopAttrib` and `PopClientAttrib` commands are used for this purpose. The commands

```c
void PushAttrib( bitfield mask );
void PushClientAttrib( bitfield mask );
```

take a bitwise OR of symbolic constants indicating which groups of state variables to push onto an attribute stack. `PushAttrib` uses a server attribute stack while `PushClientAttrib` uses a client attribute stack. Each constant refers to a group of state variables. The classification of each variable into a group is indicated in the following tables of state variables. The error `STACK_OVERFLOW` is generated if `PushAttrib` or `PushClientAttrib` is executed while the corresponding stack depth is `MAX_ATTRIB_STACK_DEPTH` or `MAX_CLIENT_ATTRIB_STACK_DEPTH` respectively. Bits set in `mask` that do not correspond to an attribute group...
6.1. QUERYING GL STATE
are ignored. The special mask values ALL_ATTRIB_BITS and CLIENT_ALL_ATTRIB_BITS may be used to push all stackable server and client state, respectively.

The commands

```c
void PopAttrib(void);
void PopClientAttrib(void);
```
reset the values of those state variables that were saved with the last corresponding PushAttrib or PopClientAttrib. Those not saved remain unchanged. The error STACK_UNDERFLOW is generated if PopAttrib or PopClientAttrib is executed while the respective stack is empty.

Table 6.3 shows the attribute groups with their corresponding symbolic constant names and stacks.

When PushAttrib is called with TEXTURE_BIT set, the priorities, border colors, filter modes, wrap modes, and other state of the currently bound texture objects (see table 6.22), as well as the current texture bindings and enables, are pushed onto the attribute stack. (Unbound texture objects are not pushed or restored.) When an attribute set that includes texture information is popped, the bindings and enables are first restored to their pushed values, then the bound texture object’s parameters are restored to their pushed values.

Operations on attribute groups push or pop texture state within that group for all texture units. When state for a group is pushed, all state corresponding to TEXTURE0 is pushed first, followed by state corresponding to TEXTURE1, and so on up to and including the state corresponding to TEXTUREK where k + 1 is the value of MAX_TEXTURE_UNITS. When state for a group is popped, texture state is restored in the opposite order that it was pushed, starting with state corresponding to TEXTUREK and ending with TEXTURE0. Identical rules are observed for client texture state push and pop operations. Matrix stacks are never pushed or popped with PushAttrib, PushClientAttrib, PopAttrib, or PopClientAttrib.

The depth of each attribute stack is implementation-dependent but must be at least 16. The state required for each attribute stack is potentially 16 copies of each state variable, 16 masks indicating which groups of variables are stored in each stack entry, and an attribute stack pointer. In the initial state, both attribute stacks are empty.

In the tables that follow, a type is indicated for each variable. Table 6.4 explains these types. The type actually identifies all state associated with the indicated description; in certain cases only a portion of this state is returned. This is the case with all matrices, where only the top entry on the stack is returned; with clip planes, where only the selected clip plane is returned; with parameters describing lights,

Table 6.3: Attribute groups
where only the value pertaining to the selected light is returned; with evaluator maps, where only the selected map is returned; and with textures, where only the selected texture or texture parameter is returned. Finally, a “–” in the attribute column indicates that the indicated value is not included in any attribute group (and thus can not be pushed or popped with `PushAttrib`, `PushClientAttrib`, `PopAttrib`, or `PopClientAttrib`).

The \( M \) and \( m \) entries for initial minmax table values represent the maximum and minimum possible representable values, respectively.

### 6.2 State Tables

The tables on the following pages indicate which state variables are obtained with what commands. State variables that can be obtained using any of `GetBooleanv`, `GetIntegerv`, `GetFloatv`, or `GetDoublev` are listed with just one of these commands – the one that is most appropriate given the type of the data to be returned. These state variables cannot be obtained using `IsEnabled`. However, state variables for which `IsEnabled` is listed as the query command can also be obtained using `GetBooleanv`, `GetIntegerv`, `GetFloatv`, and `GetDoublev`. State variables for which any other command is listed as the query command can be obtained by using that command or any of its typed variants, although information may be lost when not using the listed command. Unless otherwise specified, when floating-point state is returned as integer values or integer state is returned as floating-point values it is converted in the fashion described in section 6.1.2.

State table entries which are required only by the imaging subset (see section 3.7.2) are typeset against a gray background.

### Notes
- Table 6.20 outlines the state tables for textures in OpenGL 3.2 (Compatibility Profile) as of December 7, 2009. Each row represents a different texture command with its corresponding initial value and value type, along with a description of how the texture object is bound to the respective binding point.

Table 6.61. Miscellaneous OpenGL 3.2 (Compatibility Profile) - December 7, 2009
Appendix A

Invariance

The OpenGL specification is not pixel exact. It therefore does not guarantee an exact match between images produced by different GL implementations. However, the specification does specify exact matches, in some cases, for images produced by the same implementation. The purpose of this appendix is to identify and provide justification for those cases that require exact matches.

A.1 Repeatability

The obvious and most fundamental case is repeated issuance of a series of GL commands. For any given GL and framebuffer state \textit{vector}, and for any GL command, the resulting GL and framebuffer state must be identical whenever the command is executed on that initial GL and framebuffer state.

One purpose of repeatability is avoidance of visual artifacts when a double-buffered scene is redrawn. If rendering is not repeatable, swapping between two buffers rendered with the same command sequence may result in visible changes in the image. Such false motion is distracting to the viewer. Another reason for repeatability is testability.

Repeatability, while important, is a weak requirement. Given only repeatability as a requirement, two scenes rendered with one (small) polygon changed in position might differ at every pixel. Such a difference, while within the law of repeatability, is certainly not within its spirit. Additional invariance rules are desirable to ensure useful operation.
A.2 Multi-pass Algorithms

Invariance is necessary for a whole set of useful multi-pass algorithms. Such algorithms render multiple times, each time with a different GL mode vector, to eventually produce a result in the framebuffer. Examples of these algorithms include:

- “Erasing” a primitive from the framebuffer by redrawing it, either in a different color or using the XOR logical operation.
- Using stencil operations to compute capping planes.

On the other hand, invariance rules can greatly increase the complexity of high-performance implementations of the GL. Even the weak repeatability requirement significantly constrains a parallel implementation of the GL. Because GL implementations are required to implement ALL GL capabilities, not just a convenient subset, those that utilize hardware acceleration are expected to alternate between hardware and software modules based on the current GL mode vector. A strong invariance requirement forces the behavior of the hardware and software modules to be identical, something that may be very difficult to achieve (for example, if the hardware does floating-point operations with different precision than the software).

What is desired is a compromise that results in many compliant, high-performance implementations, and in many software vendors choosing to port to OpenGL.

A.3 Invariance Rules

For a given instantiation of an OpenGL rendering context:

**Rule 1** For any given GL and framebuffer state vector, and for any given GL command, the resulting GL and framebuffer state must be identical each time the command is executed on that initial GL and framebuffer state.

**Rule 2** Changes to the following state values have no side effects (the use of any other state value is not affected by the change):

Required:

- Framebuffer contents (all bitplanes)
- The color buffers enabled for writing
- The values of matrices other than the top-of-stack matrices
A.3. INVARIANCE RULES

- **Scissor parameters (other than enable)**
- **Writemasks (color, index, depth, stencil)**
- **Clear values (color, index, depth, stencil, accumulation)**
  - Current values (color, index, normal, texture coords, edgeflag)
  - Current raster color, index and texture coordinates.
  - Material properties (ambient, diffuse, specular, emission, shininess)

**Strongly suggested:**

- **Matrix mode**
- **Matrix stack depths**
- **Alpha test parameters (other than enable)**
- **Stencil parameters (other than enable)**
- **Depth test parameters (other than enable)**
- **Blend parameters (other than enable)**
- **Logical operation parameters (other than enable)**
- **Pixel storage and transfer state**
- **Evaluator state (except as it affects the vertex data generated by the evaluators)**
- **Polygon offset parameters (other than enables, and except as they affect the depth values of fragments)**

**Corollary 1**  
Fragment generation is invariant with respect to the state values marked with • in Rule 2.

**Corollary 2**  
The window coordinates \((x, y, \text{ and } z)\) of generated fragments are also invariant with respect to

**Required:**

- **Current values (color, color index, normal, texture coords, edgeflag)**
- **Current raster color, color index, and texture coordinates**
- **Material properties (ambient, diffuse, specular, emission, shininess)**

A.4. WHAT ALL THIS MEANS

Rule 3 The arithmetic of each per-fragment operation is invariant except with respect to parameters that directly control it (the parameters that control the alpha test, for instance, are the alpha test enable, the alpha test function, and the alpha test reference value).

Corollary 3 Images rendered into different color buffers sharing the same framebuffer, either simultaneously or separately using the same command sequence, are pixel identical.

Rule 4 The same vertex or fragment shader will produce the same result when run multiple times with the same input. The wording ‘the same shader’ means a program object that is populated with the same source strings, which are compiled and then linked, possibly multiple times, and which program object is then executed using the same GL state vector.

Rule 5 All fragment shaders that either conditionally or unconditionally assign gl_FragCoord.z to gl_FragDepth are depth-invariant with respect to each other, for those fragments where the assignment to gl_FragDepth actually is done.

A.4 What All This Means

Hardware accelerated GL implementations are expected to default to software operation when some GL state vectors are encountered. Even the weak repeatability requirement means, for example, that OpenGL implementations cannot apply hysteresis to this swap, but must instead guarantee that a given mode vector implies that a subsequent command always is executed in either the hardware or the software machine.

The stronger invariance rules constrain when the switch from hardware to software rendering can occur, given that the software and hardware renderers are not pixel identical. For example, the switch can be made when blending is enabled or disabled, but it should not be made when a change is made to the blending parameters.

Because floating point values may be represented using different formats in different renderers (hardware and software), many OpenGL state values may change subtly when renderers are swapped. This is the type of state value change that Rule 1 seeks to avoid.
Appendix B

Corollaries

The following observations are derived from the body and the other appendixes of the specification. Absence of an observation from this list in no way impugns its veracity.

1. The `CURRENT_RASTER_TEXTURE_COORDS` must be maintained correctly at all times, including periods while texture mapping is not enabled, and when the GL is in color index mode.

2. When requested, texture coordinates returned in feedback mode are always valid, including periods while texture mapping is not enabled, and when the GL is in color index mode.

3. The error semantics of upward compatible OpenGL revisions may change, and features deprecated in a previous revision may be removed. Otherwise, only additions can be made to upward compatible revisions.

4. GL query commands are not required to satisfy the semantics of the `Flush` or the `Finish` commands. All that is required is that the queried state be consistent with complete execution of all previously executed GL commands.

5. Application specified point size and line width must be returned as specified when queried. Implementation-dependent clamping affects the values only while they are in use.

7. The mask specified as the third argument to `StencilFunc` affects the operands of the stencil comparison function, but has no direct effect on the update of the stencil buffer. The mask specified by `StencilMask` has no effect on the
stencil comparison function; it limits the effect of the update of the stencil buffer.

8. Polygon shading is completed before the polygon mode is interpreted. If the shade model is FLAT, all of the points or lines generated by a single polygon will have the same color.

9. A display list is just a group of commands and arguments, so errors generated by commands in a display list must be generated when the list is executed. If the list is created in COMPILER mode, errors should not be generated while the list is being created.

10. RasterPos does not change the current raster index from its default value in an RGBA mode GL context. Likewise, RasterPos does not change the current raster color from its default value in a color index GL context. Both the current raster index and the current raster color can be queried, however, regardless of the color mode of the GL context.

11. A material property that is attached to the current color via ColorMaterial always takes the value of the current color. Attempts to change that material property via Material calls have no effect.

12. Material and ColorMaterial can be used to modify the RGBA material properties, even in a color index context. Likewise, Material can be used to modify the color index material properties, even in an RGBA context.

13. There is no atomicity requirement for OpenGL rendering commands, even at the fragment level.

14. Because rasterization of non-antialiased polygons is point sampled, polygons that have no area generate no fragments when they are rasterized in FILL mode, and the fragments generated by the rasterization of “narrow” polygons may not form a continuous array.

15. OpenGL does not force left- or right-handedness on any of its coordinates systems. Consider, however, the following conditions: (1) the object coordinate system is right-handed; (2) the only commands used to manipulate the model-view matrix are Scale (with positive scaling values only), Rotate, and Translate; (3) exactly one of either Frustum or Ortho is used to set the projection matrix; (4) the near value is less than the far value for DepthRange. If these conditions are all satisfied, then the eye coordinate system is right-handed and the clip, normalized device, and window coordinate systems are left-handed.
16. ColorMaterial has no effect on color index lighting.

17. (No pixel dropouts or duplicates.) Let two polygons share an identical edge. That is, there exist vertices A and B of an edge of one polygon, and vertices C and D of an edge of the other polygon; the positions of vertex A and C are identical; and the positions of vertex B and D are identical. Vertex positions are identical for the fixed-function pipeline if they are specified with the same input values and the state of coordinate transformations is identical when the vertices are processed; otherwise they are identical if the \texttt{gl\_Position} values output by the vertex (or if active, geometry) shader are identical. Then, when the fragments produced by rasterization of both polygons are taken together, each fragment intersecting the interior of the shared edge is produced exactly once.

18. OpenGL state continues to be modified in \texttt{FEEDBACK} mode and in \texttt{SELECT} mode. The contents of the framebuffer are not modified.

19. The current raster position, the user defined clip planes, the spot directions and the light positions for \texttt{LIGHT}$_{i}$, and the eye planes for \texttt{texgen} are transformed when they are specified. They are not transformed during a \texttt{PopAttrib}, or when copying a context.

20. Dithering algorithms may be different for different components. In particular, alpha may be dithered differently from red, green, or blue, and an implementation may choose to not dither alpha at all.

21. For any GL and framebuffer state, and for any group of GL commands and arguments, the resulting GL and framebuffer state is identical whether the GL commands and arguments are executed normally or from a display list.
Appendix C

Compressed Texture Image Formats

C.1 RGTC Compressed Texture Image Formats

Compressed texture images stored using the RGTC compressed image encodings are represented as a collection of \(4 \times 4\) texel blocks, where each block contains 64 or 128 bits of texel data. The image is encoded as a normal 2D raster image in which each \(4 \times 4\) block is treated as a single pixel. If an RGTC image has a width or height that is not a multiple of four, the data corresponding to texels outside the image are irrelevant and undefined.

When an RGTC image with a width of \(w\), height of \(h\), and block size of \(\text{block-size}\) (8 or 16 bytes) is decoded, the corresponding image size (in bytes) is:

\[
\left\lceil \frac{w}{4} \right\rceil \times \left\lceil \frac{h}{4} \right\rceil \times \text{blocksize}.
\]

When decoding an RGTC image, the block containing the texel at offset \((x, y)\) begins at an offset (in bytes) relative to the base of the image of:

\[
\text{blocksize} \times \left( \left\lceil \frac{w}{4} \right\rceil \times \left\lceil \frac{y}{4} \right\rceil + \left\lfloor \frac{x}{4} \right\rfloor \right).
\]

The data corresponding to a specific texel \((x, y)\) are extracted from a \(4 \times 4\) texel block using a relative \((x, y)\) value of

\((x \mod 4, y \mod 4)\).

There are four distinct RGTC image formats:
C.1. RGTC COMPRESSED TEXTURE IMAGE FORMATS

C.1.1 Format COMPRESSED_RED_RGTC1

Each $4 \times 4$ block of texels consists of 64 bits of unsigned red image data.

Each red image data block is encoded as a sequence of 8 bytes, called (in order of increasing address):

$$\text{red}_0, \text{red}_1, \text{bits}_0, \text{bits}_1, \text{bits}_2, \text{bits}_3, \text{bits}_4, \text{bits}_5$$

The 6 $\text{bits}_x$ bytes of the block are decoded into a 48-bit bit vector:

$$\text{bits} = \text{bits}_0 + 256 \times (\text{bits}_1 + 256 \times (\text{bits}_2 + 256 \times (\text{bits}_3 + 256 \times (\text{bits}_4 + 256 \times \text{bits}_5))))$$

$\text{red}_0$ and $\text{red}_1$ are 8-bit unsigned integers that are unpacked to red values $\text{RED}_0$ and $\text{RED}_1$ as though they were pixels with a format of LUMINANCE and a type of UNSIGNED_BYTE.

$\text{bits}$ is a 48-bit unsigned integer, from which a three-bit control code is extracted for a texel at location $(x, y)$ in the block using:

$$\text{code}(x, y) = \text{bits} \left[ 3 \times (4 \times y + x) + 2 \ldots 3 \times (4 \times y + x) + 0 \right]$$

where bit 47 is the most significant and bit 0 is the least significant bit.

The red value $R$ for a texel at location $(x, y)$ in the block is given by:
C.1. RGTC COMPRESSED TEXTURE IMAGE FORMATS

\[ R = \begin{cases} 
RED_0, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 0 \\
RED_1, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 1 \\
\frac{6\text{RED}_0+\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 2 \\
\frac{5\text{RED}_0+2\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 3 \\
\frac{4\text{RED}_0+3\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 4 \\
\frac{3\text{RED}_0+4\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 5 \\
\frac{2\text{RED}_0+5\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 6 \\
\frac{\text{RED}_0+6\text{RED}_1}{7}, & \text{red}_0 > \text{red}_1, \text{code}(x, y) = 7 \\
RED_0, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 0 \\
RED_1, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 1 \\
\frac{4\text{RED}_0+\text{RED}_1}{8}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 2 \\
\frac{3\text{RED}_0+2\text{RED}_1}{8}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 3 \\
\frac{2\text{RED}_0+3\text{RED}_1}{8}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 4 \\
\frac{\text{RED}_0+4\text{RED}_1}{8}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 5 \\
\text{RED}_{\min}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 6 \\
\text{RED}_{\max}, & \text{red}_0 \leq \text{red}_1, \text{code}(x, y) = 7 
\end{cases} \]

\( \text{RED}_{\min} \) and \( \text{RED}_{\max} \) are 0.0 and 1.0 respectively.

Since the decoded texel has a red format, the resulting RGBA value for the texel is \((R, 0, 0, 1)\).

C.1.2 Format COMPRESSED_SIGNED_RED_RGTC1

Each \(4 \times 4\) block of texels consists of 64 bits of signed red image data. The red values of a texel are extracted in the same way as COMPRESSED_RED_RGTC1 except \(\text{RED}_0, \text{RED}_1, \text{RED}_{\min}, \text{RED}_{\max}\), and \(\text{RED}_{\min}\) are signed values defined as follows:

\(\text{red}_0\) and \(\text{red}_1\) are 8-bit signed (twos complement) integers.

\[
\text{RED}_0 = \begin{cases} 
\frac{\text{red}_0}{127}, & \text{red}_0 > -128 \\
-1.0, & \text{red}_0 = -128 
\end{cases}
\]

\[
\text{RED}_1 = \begin{cases} 
\frac{\text{red}_1}{127}, & \text{red}_1 > -128 \\
-1.0, & \text{red}_1 = -128 
\end{cases}
\]

\(\text{RED}_{\min} = -1.0\)
\[RED_{\text{max}} = 1.0\]

CAVEAT for signed \(red_0\) and \(red_1\) values: the expressions \(red_0 > red_1\) and \(red_0 \leq red_1\) above are considered undefined (read: may vary by implementation) when \(red_0 = -127\) and \(red_1 = -128\). This is because if \(red_0\) were remapped to -127 prior to the comparison to reduce the latency of a hardware decompressor, the expressions would reverse their logic. Encoders for the signed red-green formats should avoid encoding blocks where \(red_0 = -127\) and \(red_1 = -128\).

C.1.3 Format COMPRESSED_RG_RGTC2

Each \(4 \times 4\) block of texels consists of 64 bits of compressed unsigned red image data followed by 64 bits of compressed unsigned green image data.

The first 64 bits of compressed red are decoded exactly like COMPRESSED_-RED_RGTC1 above.

The second 64 bits of compressed green are decoded exactly like COMPRESSED_RED_RGTC1 above except the decoded value \(R\) for this second block is considered the resulting green value \(G\).

Since the decoded texel has a red-green format, the resulting RGBA value for the texel is \((R, G, 0, 1)\).

C.1.4 Format COMPRESSED_SIGNED_RG_RGTC2

Each \(4 \times 4\) block of texels consists of 64 bits of compressed signed red image data followed by 64 bits of compressed signed green image data.

The first 64 bits of compressed red are decoded exactly like COMPRESSED_-SIGNED_RED_RGTC1 above.

The second 64 bits of compressed green are decoded exactly like COMPRESSED_SIGNED_RED_RGTC1 above except the decoded value \(R\) for this second block is considered the resulting green value \(G\).

Since this image has a red-green format, the resulting RGBA value is \((R, G, 0, 1)\).
Appendix D

Shared Objects and Multiple Contexts

This appendix describes special considerations for objects shared between multiple OpenGL contexts, including deletion behavior and how changes to shared objects are propagated between contexts.

Objects that can be shared between contexts include pixel and vertex buffer objects, display lists, program and shader objects, renderbuffer objects, sync objects, and texture objects (except for the texture objects named zero).

Framebuffer, query, and vertex array objects are not shared.

Implementations may allow sharing between contexts implementing different OpenGL versions or different profiles of the same OpenGL version (see appendix E). However, implementation-dependent behavior may result when aspects and/or behaviors of such shared objects do not apply to, and/or are not described by more than one version or profile.

D.1 Object Deletion Behavior

D.1.1 Automatic Unbinding of Deleted Objects

When a buffer, texture, or renderbuffer object is deleted, it is unbound from any bind points it is bound to in the current context, as described for DeleteBuffers, DeleteTextures, and DeleteRenderbuffers. Bind points in other contexts are not affected.
D.2. SYNC OBJECTS AND MULTIPLE CONTEXTS

D.1.2 Deleted Object and Object Name Lifetimes

When a buffer, texture, renderbuffer, or sync object is deleted, its name immediately becomes invalid (e.g. is marked unused), but the underlying object will not be deleted until it is no longer in use. A buffer, texture, or renderbuffer object is in use while it is attached to any container object or bound to a context bind point in any context. A sync object is in use while there is a corresponding fence command which has not yet completed and signaled the sync object, or while there are any GL clients and/or servers blocked on the sync object as a result of ClientWaitSync or WaitSync commands.

When a program or shader object is deleted, it is flagged for deletion, but its name remains valid until the underlying object can be deleted because it is no longer in use. A program object is in use while it is the current program in any context. A shader object is in use while it is attached to any program object.

Caution should be taken when deleting an object attached to a container object (such as a buffer object attached to a vertex array object, or a renderbuffer or texture attached to a framebuffer object), or a shared object bound in multiple contexts. Following its deletion, the object’s name may be used by any context to create a new object or returned by Gen* commands, even though the underlying object state and data may still be referred to by container objects, or in use by contexts other than the one in which the object was deleted. Such a container or other context may continue using the object, and may still contain state identifying its name as being currently bound, until such time as the container object is deleted, the attachment point of the container object is changed to refer to another object, or another attempt to bind or attach the name is made in that context. Since the name is marked unused, binding the name will create a new object with the same name, and attaching the name will generate an error. The underlying storage backing a deleted object will not be reclaimed by the GL until all references to the object from container object attachment points or context binding points are removed.

D.2 Sync Objects and Multiple Contexts

When multiple GL clients and/or servers are blocked on a single sync object and that sync object is signalled, all such blocks are released. The order in which blocks are released is implementation-dependent.
D.3 Propagating State Changes

Data is information the GL implementation does not have to inspect, and does not have an operational effect. Currently, data consists of:

- Pixels in the framebuffer.
- The contents of textures and renderbuffers.
- The contents of buffer objects.

State determines the configuration of the rendering pipeline and the driver does have to inspect.

In hardware-accelerated GL implementations, state typically lives in GPU registers, while data typically lives in GPU memory.

When the state of an object \( T \) is changed, such changes are not always immediately visible, and do not always immediately affect GL operations involving that object. Changes to an object may occur via any of the following means:

- State-setting commands, such as `TexParameter`.
- Data-setting commands, such as `TexSubImage`* or `BufferSubData`.
- Data-setting through rendering to attached renderbuffers or transform feedback operations.
- Commands that affect both state and data, such as `TexImage`* and `BufferData`.
- Changes to mapped buffer data followed by a command such as `UnmapBuffer` or `FlushMappedBufferRange`.

D.3.1 Determining Completion of Changes to an object

The object \( T \) is considered to have been changed once a command such as described in section D.3 has completed. Completion of a command \(^1\) may be determined either by calling `Finish`, or by calling `FenceSync` and executing a `WaitSync` command on the associated sync object. The second method does not require a round trip to the GL server and may be more efficient, particularly when changes to \( T \) in one context must be known to have been completed before executing commands dependent on those changes in another context.

\(^1\)The GL already specifies that a single context processes commands in the order they are received. This means that a change to an object in a context at time \( t \) must be completed by the time a command issued in the same context at time \( t + 1 \) uses the result of that change.
D.3. PROPAGATING STATE CHANGES

D.3.2 Definitions

In the remainder of this section, the following terminology is used:

- An object \( T \) is directly attached to the current context if it has been bound to one of the context binding points. Examples include but are not limited to bound textures, bound framebuffers, bound vertex arrays, and current programs.

- \( T \) is indirectly attached to the current context if it is attached to another object \( C \), referred to as a container object, and \( C \) is itself directly or indirectly attached. Examples include but are not limited to renderbuffers or textures attached to framebuffers; buffers attached to vertex arrays; and shaders attached to programs.

- An object \( T \) which is directly attached to the current context may be re-attached by re-binding \( T \) at the same bind point. An object \( T \) which is indirectly attached to the current context may be re-attached by re-attaching the container object \( C \) to which \( T \) is attached.

**Corollary:** re-binding \( C \) to the current context re-attaches \( C \) and its hierarchy of contained objects.

D.3.3 Rules

The following rules must be obeyed by all GL implementations:

**Rule 1** If the state of object \( T \) is changed in the current context while \( T \) is directly or indirectly attached, then all operations on \( T \) will use that new state in the current context.

Note: The intent of this rule is to address state changes in a single context only. The multi-context case is handled by the other rules.

Note: “Updates” via rendering or transform feedback are treated consistently with update via GL commands. Once \texttt{EndTransformFeedback} has been issued, any command in the same context that uses the results of the transform feedback operation will see the results. If a feedback loop is setup between rendering and transform feedback (see above), results will be undefined.

**Rule 2** While a container object \( C \) is bound, any changes made to \( C \)’s attachments in the current context are guaranteed to be seen. To guarantee seeing changes made in another context to objects attached to \( C \), such changes must be completed in that other context (see section D.3.1) prior to \( C \) being bound. Changes
made in another context but not determined to have completed as described in section D.3.1, or after C is bound in the current context, are not guaranteed to be seen.

**Rule 3** State changes to shared objects are not automatically propagated between contexts. If the state of a shared object T is changed in a context other than the current context, and T is already directly or indirectly attached to the current context, any operations on the current context involving T via those attachments are not guaranteed to use its new state.

**Rule 4** If the state of a shared object T is changed in a context other than the current context, T must be attached or re-attached to at least one binding point in the current context in order to guarantee that the new state of T is visible in the current context.

- **Note:** “Attached or re-attached” means either attaching an object to a binding point it wasn’t already attached to, or attaching an object again to a binding point it was already attached.

- **Note:** This rule also applies to the pointer to the data store of an object. The pointer itself is state, while the content of the data store are data, not state. To guarantee that another context sees data updates to an object, you should attach or re-attach the object in that context, since the pointer to the data store could have changed.

- **Note:** To be sure that a data update resulting from a transform-feedback operation in another context is visible in the current context, the app needs to make sure that the command `EndTransformFeedback` has completed (see section D.3.1).

- **Example:** If a texture image is bound to multiple texture bind points and the texture is modified in another context, re-binding the texture at any one of the texture bind points is sufficient to cause the modifications to be visible at all texture bind points.
Appendix E

Profiles and the Deprecation Model

OpenGL 3.0 introduces a deprecation model in which certain features may be marked as deprecated. Deprecated features are expected to be completely removed from a future version of OpenGL. Deprecated features are summarized in section E.2.

To aid developers in writing applications which will run on such future versions, it is possible to create an OpenGL 3.0 context which does not support deprecated features. Such a context is called a forward compatible context, while a context supporting all OpenGL 3.0 features is called a full context. Forward compatible contexts cannot restore deprecated functionality through extensions, but they may support additional, non-deprecated functionality through extensions.

Profiles define subsets of OpenGL functionality targeted to specific application domains. OpenGL 3.2 defines two profiles (see below), and future versions may introduce additional profiles addressing embedded systems or other domains. OpenGL 3.2 implementations are not required to support all defined profiles, but must support the core profile described below.

To enable application control of deprecation and profiles, new context creation APIs have been defined as extensions to GLX and WGL. These APIs allow specifying a particular version, profile, and full or forward compatible status, and will either create a context compatible with the request, or fail (if, for example, requesting an OpenGL version or profile not supported by the implementation).

Only the ARB may define OpenGL profiles and deprecated features.
E.1 Core and Compatibility Profiles

OpenGL 3.2 is the first version of OpenGL to define multiple profiles. The core profile builds on OpenGL 3.1 by adding features described in section H.1. The compatibility profile builds on the combination of OpenGL 3.1 with the special GL_ARB_compatibility extension defined together with OpenGL 3.1, adding the same new features and in some cases extending their definition to interact with existing features of OpenGL 3.1 only found in GL_ARB_compatibility.

It is not possible to implement both core and compatibility profiles in a single GL context, since the core profile mandates functional restrictions not present in the compatibility profile. Refer to the WGL_ARB_create_context_profile and GLX_ARB_create_context_profile extensions (see appendix I.3.68) for information on creating a context implementing a specific profile.

E.2 Deprecated and Removed Features

OpenGL 3.0 defined a set of deprecated features. OpenGL 3.1 removed most of the deprecated features and moved them into the optional GL_ARB_compatibility extension. The OpenGL 3.2 core profile removes the same features as OpenGL 3.1, while the optional compatibility profile supports all those features.

Deprecation and removed features are summarized below in two groups: features which are marked deprecated by the core profile, but have not yet been removed, and features actually removed from the core profile of the current version of OpenGL (no features have been removed from or deprecated in the compatibility profile).

Functions which have been removed will generate an INVALID_OPERATION error if called in the core profile or in a forward-compatible context. Functions which are partially removed (e.g. no longer accept some parameter values) will generate the errors appropriate for any other unrecognized value of that parameter when a removed parameter value is passed in the core profile or a forward-compatible context. Functions which are deprecated but have not yet been removed from the core profile continue to operate normally except in a forward-compatible context, where they are also removed.

E.2.1 Deprecated But Still Supported Features

The following features are deprecated, but still present in the core profile. They may be removed from a future version of OpenGL, and are removed in a forward-compatible context implementing the core profile.
E.2. DEPRECATED AND REMOVED FEATURES

- Wide lines - **LineWidth** values greater than 1.0 will generate an **INVALID_-VALUE** error.

- Global component limit query - the implementation-dependent values **MAX_VARYING_COMPONENTS** and **MAX_VARYING_FLOATS**.

E.2.2 Removed Features

- Application-generated object names - the names of all object types, such as buffer, query, and texture objects, must be generated using the corresponding **Gen*** commands. Trying to bind an object name not returned by a **Gen*** command will result in an **INVALID_OPERATION** error. This behavior is already the case for framebuffer, renderbuffer, and vertex array objects. Object types which have default objects (objects named zero), such as vertex array, framebuffer, and texture objects, may also bind the default object, even though it is not returned by **Gen***.

- Color index mode - No color index visuals are supplied by the window system-binding APIs such as GLX and WGL, so the default framebuffer is always in RGBA mode. All language and state related to color index mode vertex, rasterization, and fragment processing behavior is removed. **COLOR_INDEX** formats are also deprecated.

- OpenGL Shading Language versions 1.10 and 1.20. These versions of the shading language depend on many API features that have also been deprecated.

- **Begin** / **End** primitive specification - **Begin**, **End**, and **EdgeFlag*** (section 2.6.1); **Color***, **FogCoord***, **Index***, **Normal3***, **SecondaryColor3***, **TexCoord***, **Vertex* Vertex** (section 2.7); and all associated state in tables 6.5 and 6.6. Vertex arrays and array drawing commands must be used to draw primitives. However, **VertexAttrib* and the current vertex attribute state are retained in order to provide default attribute values for disabled attribute arrays.

able/Disable targets RESCALE_NORMAL and NORMALIZE (section 2.12.2); TexGen* and Enable/Disable targets TEXTURE_GEN_* (section 2.12.3, Material*, Light*, LightModel*, and ColorMaterial, ShadeModel, and Enable/Disable targets LIGHTING, VERTEX_PROGRAM_TWO_SIDE, LIGHTi, and COLOR_MATERIAL (sections 2.13.2 and 2.13.3; ClipPlane; and all associated fixed-function vertex array, multitexture, matrix and matrix stack, normal and texture coordinate, lighting, and clipping state. A vertex shader must be defined in order to draw primitives.

Language referring to edge flags in the current specification is modified as though all edge flags are TRUE.

Note that the FrontFace and ClampColor commands in section 2.13 are not deprecated, as they still affect other non-deprecated functionality; however, the ClampColor targets CLAMP_VERTEX_COLOR and CLAMP_FRAGMENT_COLOR are deprecated.

• Client vertex and index arrays - all vertex array attribute and element array index pointers must refer to buffer objects (section 2.9.6). The default vertex array object (the name zero) is also deprecated. Calling VertexAttribPointer when no buffer object or no vertex array object is bound will generate an INVALID_OPERATION error, as will calling any array drawing command when no vertex array object is bound.

• Rectangles - Rect* (section 2.11).

• Current raster position - RasterPos* and WindowPos* (section 2.24), and all associated state.

• Two-sided color selection (section 2.13.1) - Enable target VERTEX_PROGRAM_TWO_SIDE; OpenGL Shading Language builtins gl_BackColor and gl_BackSecondaryColor; and all associated state.

• Non-sprite points (section 3.4) - Enable/Disable targets POINT_SMOOTH and POINT_SPRITE, and all associated state. Point rasterization is always performed as though POINT_SPRITE were enabled.

• Wide lines and line stipple - LineWidth is not deprecated, but values greater than 1.0 will generate an INVALID_VALUE error; LineStipple and Enable/Disable target LINE_STIPPLE (section 3.5.2, and all associated state.

• Quadrilateral and polygon primitives - vertex array drawing modes POLYGON, QUADS, and QUAD_STRIP (section 2.6.1, related descriptions of rasterization of non-triangle polygons in section 3.6, and all associated state.
E.2. DEPRECATED AND REMOVED FEATURES

- Separate polygon draw mode - **PolygonMode** face values of **FRONT** and **BACK**; polygons are always drawn in the same mode, no matter which face is being rasterized.

- Polygon Stipple - **PolygonStipple** and Enable/Disable target **POLYGON_STIPPLE** (section 3.6.2, and all associated state.

- Pixel transfer modes and operations - all pixel transfer modes, including pixel maps, shift and bias, color table lookup, color matrix, and convolution commands and state (sections 3.7.2, 3.7.3, and 3.7.6), and all associated state and commands defining that state.

- Pixel drawing - **DrawPixels** and **PixelZoom** (section 3.7.5). However, the language describing pixel rectangles in section 3.7 is retained as it is required for **TexImage** and **ReadPixels**.

- Bitmaps - **Bitmap** (section 3.8) and the **BITMAP** external format.

- Legacy OpenGL 1.0 pixel formats - the values 1, 2, 3, and 4 are no longer accepted as internal formats by **TexImage** or any other command taking an internal format argument. The initial internal format of a texel array is **RGBA** instead of 1 (see section 3.9.1). **TEXTURE_COMPONENTS** is deprecated; always use **TEXTURE_INTERNAL_FORMAT**.

- Legacy pixel formats - all **ALPHA**, **LUMINANCE**, **LUMINANCE_ALPHA**, and **INTENSITY** external and internal formats, including compressed, floating-point, and integer variants (see tables 3.6, 3.16, 3.18, 3.20, 3.25, and 6.1); all references to luminance and intensity formats elsewhere in the specification, including conversion to and from those formats; and all associated state. including state describing the allocation or format of luminance and intensity texture or framebuffer components.

- Depth texture mode - **DEPTH_TEXTURE_MODE**. Section 3.9.16 is to be changed so that \( r \) is returned to texture samplers directly, and the OpenGL Shading Language 1.30 Specification is to be changed so that \((r, r, r, 1)\) is always returned from depth texture samplers in this case.

- Texture wrap mode **CLAMP** - **CLAMP** is no longer accepted as a value of texture parameters **TEXTURE_WRAP_S**, **TEXTURE_WRAP_T**, or **TEXTURE_WRAP_R**.

- Texture borders - the **border** value to **TexImage** must always be zero, or an **INVALID_VALUE** error is generated (section 3.9.1); all language in sec-
E.2. DEPRECATED AND REMOVED FEATURES

- Automatic mipmap generation - 

- Fixed-function fragment processing - 

- Alpha test - 

- Accumulation buffers - 

- Pixel copying - 

- Auxiliary color buffers, including 

- Context framebuffer size queries - 

- Evaluators - 

- Selection and feedback modes - 

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
E.2. DEPRECATED AND REMOVED FEATURES

- Display lists - NewList, EndList, CallList, CallLists, ListBase, GenLists, IsList, and DeleteLists (section 5.4); all references to display lists and behavior when compiling commands into display lists elsewhere in the specification; and all associated state.

- Hints - the PERSPECTIVE_CORRECTION_HINT, POINT_SMOOTH_HINT, FOG_HINT, and GENERATE_MIPMAP_HINT targets to Hint (section 5.7).

- Attribute stacks - PushAttrib, PushClientAttrib, PopAttrib, PopClientAttrib, the MAX_ATTRIB_STACK_DEPTH, MAX_CLIENT_ATTRIB_STACK_DEPTH, ATTRIB_STACK_DEPTH, and CLIENT_ATTRIB_STACK_DEPTH state, the client and server attribute stacks, and the values ALL_ATTRIB_BITS and CLIENT_ALL_ATTRIB_BITS (section 6.1.19).

- Unified extension string - EXTENSIONS target to GetString (section 6.1.4).

- Token names and queries - all token names and queries not otherwise mentioned above for deprecated state, as well as all query entry points where all valid targets of that query are deprecated state (chapter 6 and the state tables)
Appendix F

Version 3.0 and Before

OpenGL version 3.0, released on August 11, 2008, is the eighth revision since the original version 1.0. When using a full 3.0 context, OpenGL 3.0 is upward compatible with earlier versions, meaning that any program that runs with a 2.1 or earlier GL implementation will also run unchanged with a 3.0 GL implementation. OpenGL 3.0 context creation is done using a window system binding API, and on most platforms a new command, defined by extensions introduced along with OpenGL 3.0, must be called to create a 3.0 context. Calling the older context creation commands will return an OpenGL 2.1 context. When using a forward compatible context, many OpenGL 2.1 features are not supported.

Following are brief descriptions of changes and additions to OpenGL 3.0. Descriptions of changes and additions in earlier versions of OpenGL (versions 1.1, 1.2, 1.2.1, 1.3, 1.4, 1.5, 2.0, and 2.1) are omitted in this specification, but may be found in the OpenGL 3.0 Specification, available on the World Wide Web at URL http://www.opengl.org/registry/

F.1 New Features

New features in OpenGL 3.0, including the extension or extensions if any on which they were based, include:

- API support for the new texture lookup, texture format, and integer and unsigned integer capabilities of the OpenGL Shading Language 1.30 specification (GL_EXT_gpu_shader4).
- Conditional rendering (GL_NV_conditional_render).
F.2. DEPRECATION MODEL

- Fine control over mapping buffer subranges into client space and flushing modified data (GL_APPLE_flush_buffer_range).

- Floating-point color and depth internal formats for textures and renderbuffers (GL_ARB_color_buffer_float, GL_NV_depth_buffer_float, GL_ARB_texture_float, GL_EXT_packed_float, and GL_EXT_texture_shared_exponent).

- Framebuffer objects (GL_EXT_framebuffer_object).

- Half-float (16-bit) vertex array and pixel data formats (GL_NV_half_float and GL_ARB_half_float_pixel).

- Multisample stretch blit functionality (GL_EXT_framebuffer_multisample and GL_EXT_framebuffer_blit).

- Non-normalized integer color internal formats for textures and renderbuffers (GL_EXT_texture_integer).

- One- and two-dimensional layered texture targets (GL_EXT_texture_array).

- Packed depth/stencil internal formats for combined depth+stencil textures and renderbuffers (GL_EXT_packed_depthStencil).

- Per-color-attachment blend enables and color writemasks (GL_EXT_draw_buffers2).

- RGTC specific internal compressed formats (GL_EXT_texture_compression_rgtc).

- Single- and double-channel (R and RG) internal formats for textures and renderbuffers.

- Transform feedback (GL_EXT_transform_feedback).

- Vertex array objects (GL_APPLE_vertex_array_object).

- sRGB framebuffer mode (GL_EXT_framebuffer_sRGB)

F.2 Deprecation Model

OpenGL 3.0 introduces a deprecation model in which certain features may be marked as deprecated. The deprecation model is described in detail in appendix E, together with a summary of features deprecated in OpenGL 3.0.
F.3 CHANGED TOKENS

New token names are introduced to be used in place of old, inconsistent names. However, the old token names continue to be supported, for backwards compatibility with code written for previous versions of OpenGL. The new names, and the old names they replace, are shown in table F.1.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Table F.1: New token names and the old names they replace.

F.3 Changed Tokens

F.4 Change Log

Minor corrections to the OpenGL 3.0 Specification were made after its initial release.

Changes in the draft of September 23, 2008:

- Changed ClearBuffer* in section 4.2.3 to use DEPTH and STENCIL buffer names. Changed GetFramebufferAttachmentParameteriv in section 6.1.17 to accept only DEPTH and STENCIL to identify default framebuffer depth and stencil buffers, and only DEPTH_ATTACHMENT and STENCIL_ATTACHMENT to identify framebuffer object depth and stencil buffers (bug 3744).

Changes in the draft of September 18, 2008:

- Added missing close-brace to ArrayElement pseudocode in section 2.8 (bug 3897).

- Noted in section 2.17 that BeginQuery will generate an INVALID_OPERATION error when called with an existing query object name whose type does not match the specified target (bug 3712).

- Add description of gl_ClipDistance to shader outputs in section 2.14.4 and note that only one of gl_ClipVertex and gl_ClipDistance should be written by a shader (bug 3898).
• Changed `ClearBuffer*` in section 4.2.3 to indirect through the draw buffer state by specifying the buffer type and draw buffer number, rather than the attachment name; also changed to accept `DEPTH_BUFFER / DEPTH_ATTACHMENT` and `STENCIL_BUFFER / STENCIL_ATTACHMENT` interchangeably, to reduce inconsistency between clearing the default framebuffer and framebuffer objects. Likewise changed `GetFramebufferAttachmentParameteriv` in section 6.1.17 to accept `DEPTH_BUFFER / DEPTH_ATTACHMENT` and `STENCIL_BUFFER / STENCIL_ATTACHMENT` interchangeably (bug 3744).

• Add proper type suffix to query commands in tables 6.9 and 6.46 (Mark Kilgard).

• Update deprecation list in section E.2 to itemize deprecated state for two-sided color selection and include per-texture-unit LOD bias (bug 3735).

Changes in the draft of August 28, 2008:

• Sections 2.9, 2.9.3; tables 2.8, 2.9, and 6.12 - move buffer map/unmap calls into their own subsection and rewrite `MapBuffer` in terms of `MapBufferRange`. Add buffer state `BUFFER_ACCESS_FLAGS`, `BUFFER_MAP_OFFSET`, `BUFFER_MAP_LENGTH`. Make `MapBuffer` and `MapBufferRange` errors consistent (bug 3601).

• Section 2.10 - Extend `INVALID_OPERATION` error to any array pointer-setting command called to specify a client array while a vertex array object is bound, not just `VertexAttrib*Pointer` (bug 3696).

• Sections 2.16.1, 4.1.2, 4.2.1, and 4.3.4 - define initial state when a context is bound with no default framebuffer - null viewport and scissor region, draw buffer = read buffer = `NONE`, max viewport dims = `max(display size - if any, max renderbuffer size)`. Viewport/scissor language added to the GLX and WGL create context extension specs as well (bug 2941).

• Section 2.19 - define “word-aligned” to be a multiple of 4 (e.g. 32 bits) (bug 3624).

• Section 5.4.1 - add `MapBufferRange` and `FlushMappedBufferRange` to commands not compiled in display lists (bug 3704).

• Section 6.1.14 - Moved `GetBufferParameteriv` query from section 6.1.3 and changed formal argument specifying the parameter name from `value` to `pname` (side effect of bug 3697).

OpenGL 3.2 (Compatibility Profile) - December 7, 2009
Section 6.1.17 - Moved `GetFramebufferAttachmentiv` query from section 6.1.3. Querying framebuffer attachment parameters other than object type and name when no attachment is present is an `INVALID_ENUM` error. Querying texture parameters (level, cube map face, or layer) for a renderbuffer attachment is also an `INVALID_ENUM` error (note that this was allowed in previous versions of the extension but the return values were not specified; it should clearly be an error as are other parameters that don’t exist for the type of attachment present). Also reorganized the description of this command quite a bit to improve readability and remove redundancy and internal inconsistencies (bug 3697).

Section 6.1.18 - Moved `GetRenderbufferParameteriv` query from section 6.1.3 (side effect of bug 3697).

Appendix D.1 - add language to clarify that attachments to an object affect its reference count, and that object storage doesn’t go away until there are no references remaining (bug 3725).

Appendix E.2 - remove `TEXTURE_BORDER_COLOR` and `CLAMP_TO_BORDER` mode from the deprecated feature list; they were put in by accident (bug 3750).

Appendix F - Cite `GL_EXT_texture_array` instead of `GL_EXT_geometry_shader4` as the source of 1D/2D array texture functionality. Fix a typo. Add change log relative to initial 3.0 spec release.

F.5 Credits and Acknowledgements

OpenGL 3.0 is the result of the contributions of many people and companies. Members of the Khronos OpenGL ARB Working Group during the development of OpenGL 3.0, including the company that they represented at the time of their contributions, follow. Some major contributions made by individuals are listed together with their name, including specific functionality developed in the form of new ARB extensions together with OpenGL 3.0. In addition, many people participated in developing earlier vendor and `EXT` extensions on which the OpenGL 3.0 functionality is based in part; those individuals are listed in the respective extension specifications in the OpenGL Extension Registry.

Appendix G

Version 3.1

OpenGL version 3.1, released on March 24, 2009, is the ninth revision since the original version 1.0.

Unlike earlier versions of OpenGL, OpenGL 3.1 is not upward compatible with earlier versions. The commands and interfaces identified as deprecated in OpenGL 3.0 (see appendix F) have been removed from OpenGL 3.1 entirely, with the following exception:

- Wide lines have not been removed, and calling `LineWidth` with values greater than 1.0 is not an error.

Implementations may restore such removed features using the `GL_ARB_compatibility` extension discussed in section G.2.

Following are brief descriptions of changes and additions to OpenGL 3.1.

G.1 New Features

New features in OpenGL 3.1, including the extension or extensions if any on which they were based, include:

- Support for OpenGL Shading Language 1.30 and 1.40.
- Instanced rendering with a per-instance counter accessible to vertex shaders (`GL_ARB_draw_instanced`).
- Data copying between buffer objects (`GL_ARB_copy_buffer`).
- Primitive restart (`GL_NV_primitive_restart`). Because client enable/disable no longer exists in OpenGL 3.1, the `PRIMITIVE_RESTART`
G.2. DEPRECIATION MODEL

state has become server state, unlike the NV extension where it is client state. As a result, the numeric values assigned to PRIMITIVE_RESTART and PRIMITIVE_RESTART_INDEX differ from the NV versions of those tokens.

• At least 16 texture image units must be accessible to vertex shaders, in addition to the 16 already guaranteed to be accessible to fragment shaders.

• Texture buffer objects (GL_ARB_texture_buffer_object).

• Rectangular textures (GL_ARB_texture_rectangle).

• Uniform buffer objects (GL_ARB_uniform_buffer_object).

• Signed normalized texture component formats.

G.2 Deprecation Model

The features marked as deprecated in OpenGL 3.0 (see section E) have been removed from OpenGL 3.1 (with the exception of line widths greater than one, which are retained).

As described by the deprecation model, features removed from OpenGL 3.0 have been moved into the new extension GL_ARB_compatibility. If an implementation chooses to provide this extension, it restores all features deprecated by OpenGL 3.0 and removed from OpenGL 3.1. This extension may only be provided in an OpenGL 3.1 or later context version.

Because of the complexity of describing this extension relative to the OpenGL 3.1 core specification, it is not written up as a separate document, unlike other extensions in the extension registry. Instead, an alternate version of this specification document has been generated with the deprecated material still present, but marked in a distinct color.

No additional features are deprecated in OpenGL 3.1.

G.3 Change Log

Changes in the specification update of May 28, 2009:

• Update MAX_CLIP_DISTANCES from 6 to 8 in section 2.22 and table 6.51, to match GLSL (bug 4803).

• Accept null pointers in CompressedTexImage* (section 3.9.3) and treat them the same as for the corresponding TexImage* commands (bug 4863).
G.4. CREDITS AND ACKNOWLEDGEMENTS

- Relax error conditions when specifying RGTC format texture images (section 3.9.2) and subimages (section 3.9.3) so that non-power-of-two RGTC images may be specified (also see section C.1), and edits to partial tiles at the edge of such an image made (bug 4856).

- Relaxed texture magnification switch-over point calculation in section 3.9.10 (bug 4392).

- Clarify initial value of stencil value masks in section 4.1.5 and table 6.26 (bug 4378).

- Change **FramebufferTextureLayer** in section 4.4.2 to generate **INVALID_VALUE** for negative layer only if texture is non-zero (bug 4084).

- Clarify **RenderbufferStorageMultisample** language in section 4.4.2 to allow, but not require creation of multisampled integer renderbuffers with more one sample (bug 4396).

- Added language to section 6.1.4 disallowing data-type format mismatches between internal and external texture formats in **GetTexImage** (bug 4163).

- Change initial value of **FRAMEBUFFER_ATTACHMENT_TEXTURE_CUBE_MAP_FACE** in table 6.31 to **NONE** (bug 4407).

- Brought extension list in appendix I.3 up to date and correctly described extensions introduced along with OpenGL 3.0 and OpenGL 3.1 which implement subsets of new functionality in those versions to enable older hardware.

- Added missing contributors to the OpenGL 3.1 contributor list.

G.4 Credits and Acknowledgements

Appendix H

Version 3.2

OpenGL version 3.2, released on August 3, 2009, is the tenth revision since the original version 1.0.

Separate versions of the OpenGL 3.2 Specification exist for the core and compatibility profiles described in appendix E, respectively subtitled the “Core Profile” and the “Compatibility Profile”. This document describes the Compatibility Profile. An OpenGL 3.2 implementation must be able to create a context supporting the core profile, and may also be able to create a context supporting the compatibility profile.

Material specific to the compatibility profile specification is marked in a distinct color to clearly call out differences between the two profiles.

The OpenGL 3.2 core profile is upward compatible with OpenGL 3.1, but not with earlier versions (see appendices G and F).

The OpenGL 3.2 compatibility profile is upward compatible with the combination of OpenGL 3.1 and the GL_ARB_compatibility extension, as well as with all earlier versions of OpenGL.

Following are brief descriptions of changes and additions to OpenGL 3.2.

H.1 New Features

New features in OpenGL 3.2, including the extension or extensions if any on which they were based, include:

- Introduction of core and compatibility profiles, superseding the GL_ARB_compatiblity extension introduced with OpenGL 3.1.

- Support for OpenGL Shading Language 1.50.
H.2. DEPRECIATION MODEL

In addition to restoring features removed from OpenGL 3.1 core, the compatibility profile defines some additional interactions between those features and new features introduced by OpenGL 3.2.

The following features are newly deprecated by the OpenGL 3.2 core profile:

- Global component limit query - the implementation-dependent values `MAX_VARYING_COMPONENTS` and `MAX_VARYING_FLOATS`.

No features are deprecated by the OpenGL 3.2 compatibility profile.

H.3 Changed Tokens

New token names are introduced to be used in place of old, less general names. However, the old token names continue to be supported, for backwards compatibility with code written for previous versions of OpenGL. The new names, and the old names they replace, are shown in table H.1.
H.4 CHANGE LOG

<table>
<thead>
<tr>
<th>New Token Name</th>
<th>Old Token Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM_POINT_SIZE</td>
<td>VERTEX_PROGRAM_POINT_SIZE</td>
</tr>
</tbody>
</table>

Table H.1: New token names and the old names they replace.

H.4 Change Log

Minor corrections to the OpenGL 3.2 Specification were made after its initial release in the update of December 7, 2009:

- Clean up description of GL command syntax in section 2.3, generalize the list of object types in the introduction to section 2.5 instead of enumerating them all redundantly, add half float to the ArrayElement pseudocode in section 2.8, fix BindBuffer (section 2.9.1), BeginQuery (section 2.17), and BindTexture (section 3.9.14) to only generate errors for user generated names in the core profile, remove $P$ from computation of normalized device coordinates in section 2.16, increase minimum number of clip half-spaces to 8 in section 2.22, correct labelling of fragment processing selection in figure 3.1 for the compatibility profile, improve formatting and correct column heading in tables 6.20 and 6.21, and a variety of minor editorial corrections not enumerated here (Bug 5761).

- Remove “just as if they were unused” from description of names generated by GenVertexArrays, GenFramebuffers, and GenRenderbuffers in sections 2.10, 4.4.1, and 4.4.2 (Bug 5201).

- Fix duplicate label formerly applied to sections 2.12 and 2.16 (Bug 5455).

- Moved error language resulting from trying to put client pointers into VAOs from section 2.10 to section 2.8 (Bug 3975). This results in a forward reference, unfortunately.

- Remove reference to borders from texel fetch language in section 2.14.4 of the core specification (Bug 5343).

- Remove INVALID_VALUE error when passing a program object to TransformFeedbackVaryings in section 2.14.6 (Bug 5661).

- Changed number of query types from two to three in section 2.17 (Bug 5624).
H.4. CHANGE LOG

- Change flat-shading source value description from “generic attribute” to “varying” in sections 3.5.1 and 3.6.1 (Bug 5359).

- Remove leftover references in core spec sections 3.9.3 and 6.1.3 to deprecated texture border state (Bug 5579). Still need to fix gl3.h accordingly.

- Fix typo in second paragraph of section 3.9.6 (Bug 5625).

- Simplify and clean up equations in the coordinate wrapping and mipmapping calculations of section 3.9.9, especially in the core profile where wrap mode CLAMP does not exist (Bug 5615).

- Fix computation of \( u(x, y) \) and \( v(x, y) \) in scale factor calculations of section 3.9.9 for rectangular textures (Bug 5700).

- Restructure definition of texture completeness in section 3.9.12 to separate mipmap consistency from filter requirements and cover new texture target types, and simplify how completeness applies to texture fetches (section 2.14.4) and lookups (sections 2.14.4 and 3.12.2) (Bugs 4264, 5749).

- Update sampling language in sections 3.9.12, 2.14.4, and 3.12.2 to not require texture completeness when non-mipmapped access to the texture is being done (Bug 4264, based on ES bugs 4282 and 3499).

- Add fixed sample location state for multisample textures to section 3.9.13 (Bug 5454).

- Don’t use the sign of the input component in the description of dithering in section 4.1.10 (Bug 5594).

- Change error condition for certain invalid buffers to DrawBuffers in section 4.2.1 from INVALID_OPERATION to INVALID_ENUM (Bug 5576).

- Clarify error conditions in section 4.2.3 when the clear mask is zero or contains invalid bits (Bug 5567).

- Change BlitFramebuffer in section 4.3.3 so format conversion is supported only within the three equivalence classes of fixed-point and floating point buffers, unsigned integer buffers, and signed integer buffers (Bug 5577).

- Include ClientWaitSync, FenceSync, and PrimitiveRestartIndex in the commands not compiled into display lists in section 5.4.1 (for the compatibility spec only) (Bug 5091).
• Remove a reference to unreachable INVALID_OPERATION errors from the core profile only in section 6.1.2 (Bug 5365).

• Specify that compressed texture component type queries in section 6.1.3 return how components are interpreted after decompression (Bug 5453).

• Increase value of MAX_UNIFORM_BUFFER_BINDINGS and MAX_COMBINED_UNIFORM_BLOCKS in table 6.58 from 24 to 36 to reflect addition of geometry shaders (Bug 5607).

• Update sharing rule 2 in appendix D.3.3 to read sensibly (Bug 5397).

• Update sharing rule 4 in appendix D.3.3 to cover the case where an object is only attached or bound in a single place, clarify comments about transform feedback, and state that reattachment is required to guarantee seeing changes made in other contexts, but does not preclude implementations from making changes visible without reattachment (Bugs 5546, 5777).

Changes in the specification for public release on August 3, 2009:

• Public release of OpenGL 3.2.

H.5 Credits and Acknowledgements

icks, and Michelle Clark, and technical support from James Riordon, webmaster
of Khronos.org and OpenGL.org.
Appendix I

Extension Registry, Header Files, and ARB Extensions

I.1 Extension Registry

Many extensions to the OpenGL API have been defined by vendors, groups of vendors, and the OpenGL ARB. In order not to compromise the readability of the GL Specification, such extensions are not integrated into the core language; instead, they are made available online in the OpenGL Extension Registry, together with extensions to window system binding APIs, such as GLX and WGL, and with specifications for OpenGL, GLX, and related APIs.

Extensions are documented as changes to a particular version of the Specification. The Registry is available on the World Wide Web at URL

http://www.opengl.org/registry/

I.2 Header Files

Historically, C and C++ source code calling OpenGL was to #include a single header file, <GL/gl.h>. In addition to the core OpenGL API, the APIs for all extensions provided by an implementation were defined in this header.

When platforms became common where the OpenGL SDK (library and header files) were not necessarily obtained from the same source as the OpenGL driver, such as Microsoft Windows and Linux, <GL/gl.h> could not always be kept in sync with new core API versions and extensions supported by drivers. At this time the OpenGL ARB defined a new header, <GL/glext.h>, which could be
I.3. ARB EXTENSIONS

obtained directly from the OpenGL Extension Registry (see section I.1). The combination of \texttt{<GL/gl.h>} and \texttt{<GL/glext.h>} always defines all APIs for all profiles of the latest OpenGL version, as well as for all extensions defined in the Registry.

\texttt{<GL3/gl3.h>} defines APIs for the core profile of OpenGL 3.2, together with ARB extensions compatible with the core profile. It does not include APIs for features only in the compatibility profile or for other extensions.

\texttt{<GL3/gl3ext.h>} defines APIs for additional ARB, EXT, and vendor extensions compatible with the core profile, but not defined in \texttt{<GL3/gl3.h>}. Most older extensions are not compatible with the core profile.

Applications using the OpenGL 3.2 compatibility profile (see appendices H and E) should \#include the traditional \texttt{<GL/gl.h>} and \texttt{<GL/glext.h>} headers.

Applications using the core profile should \#include the new \texttt{<GL3/gl3.h>} and \texttt{<GL3/gl3ext.h>} headers introduced with OpenGL 3.1.

By using \texttt{<GL3/gl3.h>} and \texttt{<GL3/gl3ext.h>}, instead of the legacy \texttt{<GL/gl.h>} and \texttt{<GL/glext.h>}, newly developed applications are given increased protection against accidentally using a “legacy” feature that has been removed from the core profile. This can assist in developing applications on a GL implementation that supports the compatibility profile when the application is also intended to run on other platforms supporting only the core profile.

Developers should always be able to download \texttt{<GL3/gl3.h>} and \texttt{<GL3/gl3ext.h>} from the Registry, with these headers replacing, or being used in place of older versions that may be provided by a platform SDK.

I.3 ARB Extensions

OpenGL extensions that have been approved by the OpenGL Architectural Review Board (ARB) are summarized in this section. ARB extensions are not required to be supported by a conformant OpenGL implementation, but are expected to be widely available; they define functionality that is likely to move into the required feature set in a future revision of the specification.

I.3.1 Naming Conventions

To distinguish ARB extensions from core OpenGL features and from vendor-specific extensions, the following naming conventions are used:

- A unique name string of the form “GL_ARB_name” is associated with each extension. If the extension is supported by an implementation, this string
I.3. ARB EXTENSIONS

will be present in the EXTENSIONS string returned by GetString, and will be among the EXTENSIONS strings returned by GetStringi, as described in section 6.1.4.

- All functions defined by the extension will have names of the form FunctionARB

- All enumerants defined by the extension will have names of the form NAME_ARB.

- In addition to OpenGL extensions, there are also ARB extensions to the related GLX and WGL APIs. Such extensions have name strings prefixed by "GLX_" and "WGL_" respectively. Not all GLX and WGL ARB extensions are described here, but all such extensions are included in the registry.

I.3.2 Promoting Extensions to Core Features

ARB extensions can be promoted to required core features in later revisions of OpenGL. When this occurs, the extension specifications are merged into the core specification. Functions and enumerants that are part of such promoted extensions will have the ARB affix removed.

GL implementations of such later revisions should continue to export the name strings of promoted extensions in the EXTENSIONS string and continue to support the ARB-affixed versions of functions and enumerants as a transition aid.

For descriptions of extensions promoted to core features in OpenGL 1.3 and beyond, see the corresponding version of the OpenGL specification, or the descriptions of that version in version-specific appendices to later versions of the specification.

I.3.3 Multitexture

The name string for multitexture is GL_ARB_multitexture. It was promoted to a core feature in OpenGL 1.3.

I.3.4 Transpose Matrix

The name string for transpose matrix is GL_ARB_transpose_matrix. It was promoted to a core feature in OpenGL 1.3.
I.3. ARB EXTENSIONS

I.3.5 Multisample

The name string for multisample is GL_ARB_multisample. It was promoted to a core feature in OpenGL 1.3.

I.3.6 Texture Add Environment Mode

The name string for texture add mode is GL_ARB_texture_env_add. It was promoted to a core feature in OpenGL 1.3.

I.3.7 Cube Map Textures

The name string for cube mapping is GL_ARB_texture_cube_map. It was promoted to a core feature in OpenGL 1.3.

I.3.8 Compressed Textures

The name string for compressed textures is GL_ARB_texture_compression. It was promoted to a core feature in OpenGL 1.3.

I.3.9 Texture Border Clamp

The name string for texture border clamp is GL_ARB_texture_border_clamp. It was promoted to a core feature in OpenGL 1.3.

I.3.10 Point Parameters

The name string for point parameters is GL_ARB_point_parameters. It was promoted to a core feature in OpenGL 1.4.

I.3.11 Vertex Blend

Vertex blending replaces the single model-view transformation with multiple vertex units. Each unit has its own transform matrix and an associated current weight. Vertices are transformed by all the enabled units, scaled by their respective weights, and summed to create the eye-space vertex. Normals are similarly transformed by the inverse transpose of the model-view matrices.

The name string for vertex blend is GL_ARB_vertex_blend.
I.3.12 Matrix Palette

Matrix palette extends vertex blending to include a palette of model-view matrices. Each vertex may be transformed by a different set of matrices chosen from the palette.

The name string for matrix palette is GL_ARB_matrix_palette.

I.3.13 Texture Combine Environment Mode

The name string for texture combine mode is GL_ARB_texture_env_combine. It was promoted to a core feature in OpenGL 1.3.

I.3.14 Texture Crossbar Environment Mode

The name string for texture crossbar is GL_ARB_texture_env_crossbar. It was promoted to a core feature in OpenGL 1.4.

I.3.15 Texture Dot3 Environment Mode

The name string for DOT3 is GL_ARB_texture_env_dot3. It was promoted to a core feature in OpenGL 1.3.

I.3.16 Texture Mirrored Repeat

The name string for texture mirrored repeat is GL_ARB_texture_mirrored_repeat. It was promoted to a core feature in OpenGL 1.4.

I.3.17 Depth Texture

The name string for depth texture is GL_ARB_depth_texture. It was promoted to a core feature in OpenGL 1.4.

I.3.18 Shadow

The name string for shadow is GL_ARB_shadow. It was promoted to a core feature in OpenGL 1.4.

I.3.19 Shadow Ambient

Shadow ambient extends the basic image-based shadow functionality by allowing a texture value specified by the TEXTURE_COMPARE_FAIL_VALUE_ARB texture
I.3. ARB EXTENSIONS

A parameter to be returned when the texture comparison fails. This may be used for ambient lighting of shadowed fragments and other advanced lighting effects.

The name string for shadow ambient is GL_ARB_shadow_ambient.

I.3.20 Window Raster Position

The name string for window raster position is GL_ARB_window_pos. It was promoted to a core feature in OpenGL 1.4.

I.3.21 Low-Level Vertex Programming

Application-defined vertex programs may be specified in a new low-level programming language, replacing the standard fixed-function vertex transformation, lighting, and texture coordinate generation pipeline. Vertex programs enable many new effects and are an important first step towards future graphics pipelines that will be fully programmable in an unrestricted, high-level shading language.

The name string for low-level vertex programming is GL_ARB_vertex_program.

I.3.22 Low-Level Fragment Programming

Application-defined fragment programs may be specified in the same low-level language as GL_ARB_vertex_program, replacing the standard fixed-function vertex texturing, fog, and color sum operations.

The name string for low-level fragment programming is GL_ARB_fragment_program.

I.3.23 Buffer Objects

The name string for buffer objects is GL_ARB_vertex_buffer_object. It was promoted to a core feature in OpenGL 1.5.

I.3.24 Occlusion Queries

The name string for occlusion queries is GL_ARB_occlusion_query. It was promoted to a core feature in OpenGL 1.5.

I.3.25 Shader Objects

The name string for shader objects is GL_ARB_shader_objects. It was promoted to a core feature in OpenGL 2.0.
I.3.26  High-Level Vertex Programming

The name string for high-level vertex programming is GL_ARB_vertex_shader. It was promoted to a core feature in OpenGL 2.0.

I.3.27  High-Level Fragment Programming

The name string for high-level fragment programming is GL_ARB_fragment_shader. It was promoted to a core feature in OpenGL 2.0.

I.3.28  OpenGL Shading Language

The name string for the OpenGL Shading Language is GL_ARB_shading_language_100. The presence of this extension string indicates that programs written in version 1 of the Shading Language are accepted by OpenGL. It was promoted to a core feature in OpenGL 2.0.

I.3.29  Non-Power-Of-Two Textures

The name string for non-power-of-two textures is GL_ARB_texture_non_power_of_two. It was promoted to a core feature in OpenGL 2.0.

I.3.30  Point Sprites

The name string for point sprites is GL_ARB_point_sprite. It was promoted to a core feature in OpenGL 2.0.

I.3.31  Fragment Program Shadow

Fragment program shadow extends low-level fragment programs defined with GL_ARB_fragment_program to add shadow 1D, 2D, and 3D texture targets, and remove the interaction with GL_ARB_shadow.

The name string for fragment program shadow is GL_ARB_fragment_program_shadow.

I.3.32  Multiple Render Targets

The name string for multiple render targets is GL_ARB_draw_buffers. It was promoted to a core feature in OpenGL 2.0.
I.3.33 Rectangular Textures

Rectangular textures define a new texture target `TEXTURE_RECTANGLE_ARB` that supports 2D textures without requiring power-of-two dimensions. Rectangular textures are useful for storing video images that do not have power-of-two sizes (POTS). Resampling artifacts are avoided and less texture memory may be required. They are also useful for shadow maps and window-space texturing. These textures are accessed by dimension-dependent (aka non-normalized) texture coordinates.

Rectangular textures are a restricted version of non-power-of-two textures. The differences are that rectangular textures are supported only for 2D; they require a new texture target; and the new target uses non-normalized texture coordinates.

The name string for texture rectangles is `GL_ARB_texture_rectangle`. It was promoted to a core feature in OpenGL 3.1.

I.3.34 Floating-Point Color Buffers

Floating-point color buffers can represent values outside the normal [0, 1] range of colors in the fixed-function OpenGL pipeline. This group of related extensions enables controlling clamping of vertex colors, fragment colors throughout the pipeline, and pixel data read back to client memory, and also includes WGL and GLX extensions for creating frame buffers with floating-point color components (referred to in GLX as `framebuffer configurations`, and in WGL as `pixel formats`).

The name strings for floating-point color buffers are `GL_ARB_color_buffer_float`, `GLX_ARB_fbconfig_float`, and `WGL_ARB_pixel_format_float`. `GL_ARB_color_buffer_float` was promoted to a core feature in OpenGL 3.0.

I.3.35 Half-Precision Floating Point

This extension defines the representation of a 16-bit floating point data format, and a corresponding `type` argument which may be used to specify and read back pixel and texture images stored in this format in client memory. Half-precision floats are smaller than full precision floats, but provide a larger dynamic range than similarly sized (short) data types.

The name string for half-precision floating point is `GL_ARB_half_float_pixel`. It was promoted to a core feature in OpenGL 3.0.
I.3.36 Floating-Point Textures

Floating-point textures stored in both 32- and 16-bit formats may be defined using new internalformat arguments to commands which specify and read back texture images.

The name string for floating-point textures is GL_ARB_texture_float. It was promoted to a core feature in OpenGL 3.0.

I.3.37 Pixel Buffer Objects

The buffer object interface is expanded by adding two new binding targets for buffer objects, the pixel pack and unpack buffers. This permits buffer objects to be used to store pixel data as well as vertex array data. Pixel-drawing and reading commands using data in pixel buffer objects may operate at greatly improved performance compared to data in client memory.

The name string for pixel buffer objects is GL_ARB_pixel_buffer_object. It was promoted to a core feature in OpenGL 2.1.

I.3.38 Floating-Point Depth Buffers

The name string for floating-point depth buffers is GL_ARB_depth_buffer_float. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_NV_depth_buffer_float extension, and is provided to enable this functionality in older drivers.

I.3.39 Instanced Rendering

The name string for instanced rendering is GL_ARB_draw_instanced. It was promoted to a core feature in OpenGL 3.1.

I.3.40 Framebuffer Objects

The name string for framebuffer objects is GL_ARB_framebuffer_object. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_EXT_framebuffer_object, GL_EXT_framebuffer_multisample, and GL_EXT_framebuffer_blit extensions, and is provided to enable this functionality in older drivers.

I.3.41 sRGB Framebuffers

The name string for sRGB framebuffers is GL_ARB_framebuffer_sRGB. It was promoted to a core feature in OpenGL 3.0. This extension is equivalent to new
core functionality introduced in OpenGL 3.0, based on the earlier GL_EXT_framebuffer_sRGB extension, and is provided to enable this functionality in older drivers.

To create sRGB format surface for use on display devices, an additional pixel format (config) attribute is required in the window system integration layer. The name strings for the GLX and WGL sRGB pixel format interfaces are GLX_ARB_framebuffer_sRGB and WGL_ARB_framebuffer_sRGB respectively.

### I.3.42 Geometry Shaders

This extension defines a new shader type called a *geometry shader*. Geometry shaders are run after vertices are transformed, but prior to the remaining fixed-function vertex processing, and may generate new vertices for, or remove vertices from the primitive assembly process.

The name string for geometry shaders is GL_ARB_geometry_shader4.

### I.3.43 Half-Precision Vertex Data

The name string for half-precision vertex data GL_ARB_half_float_vertex. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_NV_half_float extension, and is provided to enable this functionality in older drivers.

### I.3.44 Instanced Rendering

This instanced rendering interface is a less-capable form of GL_ARB_draw_instanced which can be supported on older hardware.

The name string for instance rendering is GL_ARB_instanced_arrays.

### I.3.45 Flexible Buffer Mapping

The name string for flexible buffer mapping is GL_ARB_map_buffer_range. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_APPLE_flush_buffer_range extension, and is provided to enable this functionality in older drivers.

### I.3.46 Texture Buffer Objects

The name string for texture buffer objects is GL_ARB_texture_buffer_object. It was promoted to a core feature in OpenGL 3.1.
I.3. ARB EXTENSIONS

I.3.47 RGTC Texture Compression Formats

The name string for RGTC texture compression formats is GL_ARB_texture_compression_rgtc. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_EXT_texture_compression_rgtc extension, and is provided to enable this functionality in older drivers.

It was promoted to a core feature in OpenGL 3.0.

I.3.48 One- and Two-Component Texture Formats

The name string for one- and two-component texture formats is GL_ARB_texture_rg. It was promoted to a core feature in OpenGL 3.0. This extension is equivalent to new core functionality introduced in OpenGL 3.0, and is provided to enable this functionality in older drivers.

I.3.49 Vertex Array Objects

The name string for vertex array objects is GL_ARB_vertex_array_object. This extension is equivalent to new core functionality introduced in OpenGL 3.0, based on the earlier GL_APPLE_vertex_array_object extension, and is provided to enable this functionality in older drivers.

It was promoted to a core feature in OpenGL 3.0.

I.3.50 Versioned Context Creation

Starting with OpenGL 3.0, a new context creation interface is required in the window system integration layer. This interface specifies the context version required as well as other attributes of the context.

The name strings for the GLX and WGL context creation interfaces are GLX_ARB_create_context and WGL_ARB_create_context respectively.

I.3.51 Uniform Buffer Objects

The name string for uniform buffer objects is GL_ARB_uniform_buffer_object. This extension is equivalent to new core functionality introduced in OpenGL 3.1 and is provided to enable this functionality in older drivers.

I.3.52 Restoration of features removed from OpenGL 3.0

OpenGL 3.1 removes a large number of features that were marked deprecated in OpenGL 3.0 (see appendix G.2). GL implementations needing to maintain
these features to support existing applications may do so, following the depreca-
tion model, by exporting an extension string indicating those features are present. Applications written for OpenGL 3.1 should not depend on any of the features corresponding to this extension, since they will not be available on all platforms with 3.1 implementations.

The name string for restoration of features deprecated by OpenGL 3.0 is GL_ARB_compatibility.

The profile terminology introduced with OpenGL 3.2 eliminates the necessity for evolving this extension. Instead, interactions between features removed by OpenGL 3.1 and new features introduced in later OpenGL versions are defined by the compatibility profile corresponding to those versions.

I.3.53 Fast Buffer-to-Buffer Copies

The name string for fast buffer-to-buffer copies is GL_ARB_copy_buffer. This extension is equivalent to new core functionality introduced in OpenGL 3.1 and is provided to enable this functionality in older drivers.

I.3.54 Shader Texture Level of Detail Control

The name string for shader texture level of detail control is GL_ARB_shader_texture_lod. This extension is equivalent to new core functions introduced in OpenGL Shading Language 1.30 and is provided to enable this functionality in older versions of the shading language.

I.3.55 Depth Clamp Control

The name string for depth clamp control is GL_ARB_depth_clamp. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.56 Base Vertex Offset Drawing Commands

The name string for base vertex offset drawing commands is GL_ARB_draw_elements_base_vertex. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.
I.3.57 Fragment Coordinate Convention Control

The name string for fragment coordinate convention control is GL_ARB_fragment_coord_conventions. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.58 Provoking Vertex Control

The name string for provoking vertex control is GL_ARB_provoking_vertex. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.59 Seamless Cube Maps

The name string for seamless cube maps is GL_ARB_seamless_cube_map. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.60 Fence Sync Objects

The name string for fence sync objects is GL_ARB_sync. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.61 Multisample Textures

The name string for multisample textures is GL_ARB_texture_multisample. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.62 BGRA Attribute Component Ordering

The name string for BGRA attribute component ordering is GL_ARB_vertex_array_bgra. This extension is equivalent to new core functionality introduced in OpenGL 3.2 and is provided to enable this functionality in older drivers.

I.3.63 Per-Buffer Blend Control

The blending interface is extended to specify blend equation and blend function on a per-draw-buffer basis.
The name string for per-buffer blend control is `GL_ARB_draw_buffers_blend`.

### I.3.64 Sample Shading Control

Sample shading control adds the ability to request that an implementation use a minimum number of unique sets of fragment computation inputs when multisampling a pixel.

The name string for sample shading control is `GL_ARB_sample_shading`.

### I.3.65 Cube Map Array Textures

A cube map array texture is a two-dimensional array texture that may contain many cube map layers. Each cube map layer is a unique cube map image set.

The name string for cube map array textures is `GL_ARB_texture_cube_map_array`.

### I.3.66 Texture Gather

Texture gather adds a new set of texture functions (textureGather) to the OpenGL Shading Language that determine the $2 \times 2$ footprint used for linear filtering in a texture lookup, and return a vector consisting of the first component from each of the four texels in the footprint.

The name string for texture gather is `GL_ARB_texture_gather`.

### I.3.67 Texture Level-Of-Detail Queries

Texture level-of-detail queries adds a new set of fragment shader texture functions (textureLOD) to the OpenGL Shading Language that return the results of automatic level-of-detail computations that would be performed if a texture lookup were to be done.

The name string for texture level-of-detail queries is `GL_ARB_texture_query_lod`.

### I.3.68 Profiled Context Creation

Starting with OpenGL 3.2, API profiles are defined. Profiled context creation extends the versioned context creation interface to specify a profile which must be implemented by the context.
The name strings for the GLX and WGL profiled context creation interfaces are `GLX_ARB_create_context_profile` and `WGL_ARB_create_context_profile` respectively.
